Maciej:
I looked at Deal4Free, but could not see how they let you download their historical quotes. What is your experience in comparing their historical quotes with the prices actually downloadable from, say, Tradestation or E-Signal? I would need the historical prices to test an actual trading strategy simulation with NST, to see what effect their slippage really has on my returns.

On 10/28/2004 5:30:02 PM Maciej wrote:
Steve, you want to compare with deal4free - their trading software is pretty neat, the charting less so. I always get the price quoted but you need to be pretty quick. Like I say the biggest issue is that their prices are "synthetic" with the spread slanted according to the way their software thinks the price is going so its dearer to buy in a rising market and dearer to sell in a falling market. I don't think its economic for anything but small position trades.

On 10/26/2004 9:16:13 PM Steve Eberbach wrote:
Thanks for the other sites' names. I will check them out. Yes, the commission is quite steep, but I thought it much better than options, where open interest is only about 2000 to 10000 contracts maximum, and spreads run about a dollar per share.

I thought that by tracking their "valid price" to see what side of the bid/ask from Tradestation they are running, I could calculate their slippage and simulate it quite exactly. The only problem I have is the ten-second delay, which requires your trades be done in a quiet market. That is not a problem for me, since I avoid the situations where I risk a lot of bad fills.

I have written to them asking questions, but they have not responded. In particular, I asked if their realtime "valid-prices" are the prices I can execute, and if they are what they provide as historical data. They claim I can execute a fixed price in a ten-second window without change. So if my order transit is less than ten seconds, I get an exact fill, regardless of what the market does while my order is being transmitted. If their "valid price" hits my limits, my orders should execute. I should also be able to get market open and close minus their spread on the first side of the trade only, and exact fill on the exit. Their silence is not a good sign, but I still hope to learn more, since if this grows like the FOREX ads are growing in the magazines and press, this business model will be a retail brokerage competing ground due to the ease of normalizing various instruments to a common (standard) trading simulation model. Also I hate the execution of options in my experience, and would tolerate quite a large commission for a faster more liquid offering of leverage services on common stocks. The stock futures still seem a bit thin to me. Fifty pros all noticing my lonely little order, and competing to see if they can get my stop. I would prefer their making me an offer good for a time, and if I like it I can take it. I want to set up small portfolios which can be dynamically optimized. And if their computers are set up with a rigid trading model, their prices versus other quote sources might become a useful trading indicator.

Of course, if I hear reports from serious traders that they are a rigged scam house, I can spare myself the anguish of yet another what you see is not what you get. And I am fearful of them disappearing overnight, saying suddenly they are "under investigation, please be patient", meanwhile the phones are disconnected.

Steve,

Dukes looks like a variation on so called spread betting that's popular in the UK - another site is the CMC Deal4Free. The interest in these is essentially based on the level of spread - when a market is liquid their spread is small and therefore interesting. However this spread can become bigger than the cost of a contract say for the mini DJ as it becomes progressively less advantageous compared to a normal broker as you increase the bet size. Another reason for these types of sites' popularity is that for UK residents all gains are tax free which is not the case for normal brokers. The biggest issue with them from a NSDT perspective is the data can only be approximated as they do not provide data downloads of their bid / offer prices which in my experience are not a simple question of a couple of pips either side of a say Esignal price. Their spreads tend to be slanted against you depending which way they think the market is going so their use for day trading is not compelling.

On 10/23/2004 6:05:05 PM Steve Eberbach wrote:
A feature I want to see added in ver 5.0 is the ability to specify the cost of staying in a trade overnight, usually expressed as a percentage, as is done for daytrading brokers.

The trading site "Dukascopy" http://www.dukascopy.com/english/welcome/ allows trading stocks in the same style as FOREX, specifying spread in "pips", or Percent points, using large leverage as is typical in FOREX.
This is an interesting and quite appealing alternative to the larger spreads and more complicated spread structure involved with using options, and is certainly easier to simulate in a computer for the purpose of deciding tradability.

Their commission is an entry spread percent charge, plus an overnight percent charge. These charges vary with the instrument traded.

If more brokerages move to this paradigm in the near future, and I'll bet it will happen soon, it would be cool to be able to simulate this in the costs dialog of NST.

There is no way of downloading data in any of the known formats. What I've done is to set the spread as the cost when working with NSDT. I use the commission screen to set this spread - If I take for example the DJ - their typical spread is 5 points so I'll use 10 to buy or to sell. This makes my simulation tougher than real life. Whilst I don't have the historical data to do an exact comparison, twice the spread covers the "stretch" of the spread. Another factor to consider is their actual liquidity in a given stock/index. If you are dealing in the less popular stocks the spread will typically be larger (expected) but their stretch also as they will offset your trade against others or if necessary in the real market. All in all this type of system is in my opinnion ill suited for day trading more for swing/position trading.

Re: Cost of Staying in Trade Overnight

Date :11/6/2004 2:45:20 PM Poster : Steve Eberbach

Thanks, Darek, I appreciate that. When I am ready, I'll get back with you.

For Now, I am still comparing the prices from Dukascopy, which are freely downloadable from their site for import into Excel, with the spot prices and the futures prices from TradeStation, who is presently a broker for me, and primary data supplier. Unfortunately this is tedious work and is taking me some time.

As Maciej says, this trading of "Contracts for Difference", (by the way, the best keyword I have found for searching thru Google for new brokers of this type of derivatives) seems best suited for swing trades which by nature often are kept overnight.

What I will need in the way of historical data later on, is samples of the data from the various vendors of "Synthetic Price Data" which includes the "slants" Maciej mentions, so I can see if their slants ruin my limit orders. I could get data from Dukascopy, but not Deal4Free.

I got a reply from Dukascopy and I quote some information from their letter:

"...the price that we use in our system for each 10 seconds is (high+low)/2 of the last 10 sec candle. Also the 10 sec delay is not included in our historical files (if you are talking about our CSV data). You can simulate this delay yourself by activating your trading orders at the price of the next 10 sec candle. As to our price quotes, they are different from the quotes supplied other quoters by a few pips: we take these into account while generating our quotes. Finally, our stop loss/take profit orders are treated the same as regular orders in terms of commissions. There is a small extra charge for Price Guarantee orders (they guarantee opening/closing an order at an exact price; our regular orders including stop loss/take profit orders open/close at a price of the next 10 sec price tick). The value of this extra charge can be viewed while generating such orders from base-DDS.
We hope this was of help..."

My swing trading strategy relies on using limit estimates to get my orders ahead of other traders' stop orders, so I will get filled when my anticipated limit gets matched against the stoporders put in after my limits are put in. I am afraid that the traders working closer to the data vendors might see my orders and match theirs (inhouse traders) and skip over mine, unless I can leave enough money on the table so that there are enough stop orders past my price that I am sure to get filled.

So the historical data I am looking closely at is what their reported Highs and Lows are in comparison with other data sources, in various time frames, as well as how honestly they report the volume in a timely manner, so I can calculate the liquidity of the market near these highs and lows. I am interested in whether others in this forum have done any such data checking, and what they found out.

Candlestick Indicator from Daniel Lyons

Date :11/5/2004 3:13:24 PM Poster : Harlan Mao

Hi every one,

I just purchased the NeuroShell Trader. I am new here.
I saw an article about Candlestick Indicator by Daniel Lyons.
There is a formula:
100 * (EMA(EMA(Close-Open,r),s)) / (EMA(EMA(High-Low,r),s))

Can Daniel or anyone here tell me what are r and s in the formula?

Thanks and best regards,

Harlan

Re: Candlestick Indicator from Daniel Lyons

Date :11/8/2004 1:17:45 PM Poster : JackR

Harlan:

I assume you are refering to the "Candlestick Indicator" article in the User Tips section of this site.

If you will open the article and look at chart's upper right hand you'll see the expression "BlauCSI(Close,Open,32,32,High,Low,32,32,32,32,100)". r and s are 32 and 32.

Efficient template development

Date :11/13/2004 10:17:24 AM Poster : Phil Greenwood

I've been using NSDT for several months now; it's an exceptional piece of software in many ways, but I have grown frustrated with the menu driven approach to building templates.

For me this is perhaps uniquely cumbersome because I'm working a virtual net client remotely (in Nigeria), and the local end of the connection to my server - that has the NSDT software installed and faster data connections - is low.

Is there an alternative technique for creating templates so that I can write them remotely and then transfer the files to my server?

Thanks,
Phil Greenwood

Re: Efficient template development

Date :11/13/2004 2:20:36 PM Poster : Maciej

I would have suggested unauthorizing the software on you server and reauthorizing it on your local PC. Developing and then reversing the authorization when you need to be connected to a faster data link. I would have thought that devloping templates didn't require a fast link.

On 11/13/2004 10:17:24 AM Phil Greenwood wrote:

Re: Efficient template development

Date :11/14/2004 9:47:16 AM Poster : Phil Greenwood

Perhaps - a good suggestion; it's a solution I've considered, and I will do it if I can't get the more general issue of the cumbersome template development interface resolved. (No offense intended to the developers of this superb product - its a really minor issue).

Phil

I've been using NSDT for several months now; it's an exceptional piece of software in many ways, but I have grown frustrated with the menu driven approach to building templates.

For me this is perhaps uniquely cumbersome because I'm working a virtual net client remotely (in Nigeria), and the local end of the connection to my server - that has the NSDT software installed and faster data connections - is low.

Is there an alternative technique for creating templates so that I can write them remotely and then transfer the files to my server?

Thanks,
Phil Greenwood

PowerBasic / Neuroshell Integer array passing BYREF

Date :11/15/2004 8:10:40 AM Poster : Phil Greenwood

Realizing that one results of my DLL routines was an integer array rather than a single array, as I had previously coded it, I change the code so that it passed a reference to an integer array back to Neuroshell - remembering to change the relevant settings in Neuroshell to ByRef Integer - and was surprised to find that it didn't like me doing it; the results were most peculiar.

Looking back, I deduced it was the first time I'd tried to pass an integer array back by reference to Neuroshell, so I'd like to ask if there's something I should know?

Are the lengths of Neuroshell / PowerBasic integers different?

Maybe it's something else?

I know the question is wide open, but there's a strong possibility someone here has trodden this path before, and recognizes the problem.

Also, along the same lines in PowerBasic, I've written a few subs in my DLL that are exported, and work fine, but now want to call them internally...I'm looking for advice on how to handle passing pointers to internal arrays and to external memory blocks...

Thanks in advance,
Phil

Re: PowerBasic / Neuroshell Integer array passing BYREF

Date :11/19/2004 5:41:25 PM Poster : Ward.net Webmaster

We aren't sure what happened, but here is our strong advice: Pass timeseries datastreams as double* byref. The Powerbasic type is pound sign for floating point double precision. Single precision floating point is OK too, but don't use integers. Pass counts, lookback periods, etc as long integers byval. The Powerbasic type is ampersand. One of our examples shows short integers, but that example was done before we had the DayTrader, where it is likely there will be more than 32767 bars.

Re: PowerBasic / Neuroshell Integer array passing BYREF

Date :11/22/2004 9:05:19 AM Poster : Phil Greenwood

Thank you, that is indeed the information I needed. I have two further questions, which are related to this:

1) Is there a NULL output value for long integers?

2) Is there a resource that I've missed that answers these types of questions?

Many thanks,
Phil Greenwood

There is no null for integers - since integers don't have fractions we did not think they should be used for time series. Most of the documentation for DLLs is on this site in "New and upated examples" and "Changes in Documentation" All of the examples use floating point and show you how to use pointers if appropriate for the laguage you are using. There may also be some scattered info in the Tips section too.

Re: PowerBasic / Neuroshell Integer array passing BYREF

Date :11/25/2004 5:24:03 AM Poster : Phil Greenwood

Thanks again. For your information, the reason I'm using a time series as integers is to describe a measure of time (in discrete bars) since an event. So the reason I'd want a null value is when I haven't detected such an event yet.

Regarding the pointers, the none of the examples in that section showed what I was looking for - specifically, how to call a subroutine written for integration with Neuroshell from another subroutine written for integration with Neuroshell - passing all the inputs, but giving a different output time series array for further processing. This is useful if you want to build up complexity by testing modules of code one at a time, and essential if you want to do things that are even moderately complex.

For other's reference, here is a workable answer using the Byref :

SUB Routine1 ALIAS "Routine1" (BYVAL in_array AS SINGLE PTR, BYVAL out_array AS SINGLE PTR, BYVAL cnt AS INTEGER) EXPORT

DIM internal_array(cnt-1)

CALL Routine2(BYVAL in_array, BYREF internal_array(0), BYVAL cnt)

' Here is your code that would (presumably) further process internal_array and assign values to out_array.

END SUB

The second exported routine would be of the same declaration structure, so it too could be called from Neuroshell. Simple when you know it, complicated to figure out from scratch - every uncertainty complicates debugging exponentially.

There are some other bits of advice I received from the good folks at the PowerBasic forum about debugging...my thanks to Micheal Mattias for this info:

If you are using Pb/win 7+, there's a FAQ in the [PowerBasic] FAQ forum re using TRACE to find errors. Looks like you should run that. That will show you exactly where problems occur.

Also try this: make sure you are using #ERROR DEBUG ON and #REGISTER NONE, then run outside the stepping debugger.

Also: instead of calling a DLL, debug the Routine in a single EXE.

You can use something like this in your code..

```
%DEBUG = 0|1
#IF %DEBUG
#COMPILE EXE
#ELSE
#COMPLILE DLL
#ENDIF

<common stuff>

#IF %DEGBUG
FUNCTION PBMain() put test code here ....
#ELSE FUNCTION LibMain ...
#ENDIFFUNCTION Routine1 ( ....)
```

This more or less duplicates advice in this forum about debugging PowerBasic code, but is more convenient to switch on and off.

Stocks and Commodities Magazine Tips and Trading Strategy Walk Forward

Date :11/19/2004 5:04:14 PM Poster : Steve Eberbach

I have noticed that most of the Stocks and Commodities tips use the Trading Strategy Wizard, and for NST Pro users, encourage experimentation with the Genetic Optimizer.

These tips, in my opinion, are among the best educational tools available for NeuroShell Trader, and are worth so much I would recommend buying all the back issues of Stocks and Commodities, just to read the articles and illustrate them with your own favorite trading Instruments and time scales using NST to draw your illustrations!

So here is another tip. This needs to be done with a spreadsheet, but it is a worthwhile educational experience, if you are doing learning instead of real-time trading.

Export a chart to your spreadsheet, using the price series chart you want to study further. In the spreadsheet, shift all your prices forward a period of time, for example one year, and "save as" symbol xxx-1.csv -- Repeat several times: creating xxx-2.csv, xxx-3.csv, and so forth. The same dates will contain older prices, one year delayed, two year delayed, etc. It makes sense, when you export to .csv files from the spreadsheet, to export a shorter range of time in each chart, so the last export contains your first imported data.

Put these in a folder in your miscellaneous data category along with your original up-to-date xxx.csv file. Then make a new chart, (xxx walkforwards), by first loading xxx.csv, then further loading the delayed charts, all having the date range of the primary chart page, but containing "walkforwards" as illustrated in the NST documentation. (I really call them Walkbackwards).

When you optimize a trading strategy with the Trading Strategy Wizard, the optimizer will then optimize all your delayed chart pages, calculate the followup "current backtests" and when you click on the various chart pages with the pulldown listbox at the top of your display window, the chart will switch plots to show you how all the walkforwards look so you can compare them. While this is tedious work to set up, I find it worthwhile, since it creates a sort of template chart which you no longer have to manually walk backward to see how consistently the trading strategy works using various time frames for optimizing and paper trading. Just plop in your Stocks and Commodities Magazine Tips trading strategies and indicators and run them once on your delayed set of chart pages of your favorite trading instrument.

Now, if only the new version 5 Trading Strategy Wizard would add a few checkboxes: "save best current backtest", "save best optimal backtest", "save best combined backtest", or dare I even ask?, "save best N current backtests". Then you could set the wizard to optimize across all chart pages, save the best current backtest (average), and voila! you have found a trading strategy which generalized best on the paper trading just after each optimization period.

This may work as a quick way for the developers of Ver. 5 to implement Trading Strategy Wizard walkforwards.

No optimal solution message

Date :11/23/2004 7:34:57 AM Poster : Phil Greenwood

I've recently developed some tools focussed on using the GA for high yeild set-up pattern identification and I'm running into the "No Optimal Solution - Try setting less restrictive parameters and settings" message. However, I'm intentionally being unrestrictive, to the extent where it's possible I could be accused of trying to "boil the ocean".

Is it possible that the GA isn't finding anything that produces a profitable trades because of too many degrees of freedom in my approach, but gives me the same message? Can it tell the difference?

It's also possible that my approach is complex enough for me to be unintentionally restrictive - that is I've made a mistake in the set-up - so clearing this question up would tell me in which direction to look.

Many thanks,
Phil Greenwood

Newbie looking to learn on stocks/futures

Date :11/25/2004 7:18:54 AM Poster : danno

Hello-

I'm new to the Trader, and I understand that it does best with instruments that are volatile and tend to cycle. Does anyone have suggestions as to some stocks or commoditites that I can take a look at as recent examples?

Not looking for any major secrets here...just some tips as to which instruments get started with so that I can get a feel for the Trader!

Thanks much,

danno

You'll probably be able to recognise visually the stocks in them that are likely candidates and also confirm your ideas with some simple indicators among which ATR which can give the volatility. Only other caveat is to make sure that there is liquidity in that stock using volume. Otherwise you're on the right road.

Adding Text to a Chart

Date :11/27/2004 7:59:37 AM Poster : John Hegarty

Is there any way that I could append/include text to/in a chart. It would be helpful to be able to jot down initial design objectives etc together with changes made for each iteration. Clearly I can do this outside NST, but from within?

Re: Adding Text to a Chart

Date :11/27/2004 9:36:08 AM Poster : Ward.net Webmaster

Not now but that happens to already be in release 5.0.

On 11/27/2004 7:59:37 AM John Hegarty wrote:

QQQ's Become QQQQ on NASDAQ

Date :11/29/2004 8:45:16 PM Poster : John Gotwals

On December 1 the QQQs will have their listing transferred to the NASDAQ National Market under the trading symbol QQQQ.

My data feed is Quote.com, and I am wondering what the ramifications are for using QQQ in a model on NeuroShell Trader Pro when part of the data is labeled QQQ and part is labeled QQQQ.

Has anyone had any experience with something like this, and if so, what advice do you have?

Re: QQQ's Become QQQQ on NASDAQ

Date :11/30/2004 3:43:38 PM Poster : Ward.net Webmaster

QQQ is still going to be in some kind of existence as far as we have been able to find out. Quote.com says they will still be sending data for QQQ (we'll see tomorrow!). However, even if QQQ still exists on Quote.com we would expect volume levels to be less as some people switch to QQQQ. So beware if your models depend on volume indicators. Hopefully they will convert historical QQQ data to QQQQ.

eSignal's forum posts indicate they will switch to QQQQ and that they will convert historical data, so we guess they will not have QQQ tomorrow. In that case, you should be able to easily switch from QQQ to QQQQ via add/remove chart pages.

If you want to start using QQQQ and you want to append it to historical QQQ data, you should load QQQ tonight and export a text file of all your data. Then rename the text file QQQQ. Put it in a folder and then Add Directory to that folder in NeuroShell. NeuroShell should blend the two together. However, there will still be volume issues as the QQQQ volume level may be different than the old QQQ levels.

If you go to download historical QQQQ data tomorrow, and it comes, then we should assume the vendors just transferred the QQQ historical dataover. In that case, all you should ahve to do is add/remove chart pages.

If you are using QQQ as Other Instrument Data, you will have to just replace it with QQQQ if QQQ doesn't stay around.

The more we think about this, the more we think Quote.com and other vendors will follow eSignal and convert all historical QQQ data to QQQQ. If your vendor doesn't add QQQ historical to QQQQ, you should complain, because they should.

This morning Dec 1 we find that Prophet.net and eSignal have both merged the old QQQ data into QQQQ. Quote.com did not. They could, however, if they get enough pressure. We recommend all Quote.com users call Lycos and complain that QQQQ has no historical data. One number is 781-370-3456

Its a bit sad when one has to resort to such tactics to "persuade" a data supplier to do the obvious and necessary. Rather than put pressure on Quote.com to change, users should vote with their feet and move to another more profesional data provider.

If you go to download historical QQQQ data tomorrow, and it comes, then we should assume the vendors just transferred the QQQ historical dataover. In that case, all you should ahve to do is add/remove chart pages.

If you are using QQQ as Other Instrument Data, you will have to just replace it with QQQQ if QQQ doesn't stay around.

Date :12/1/2004 3:54:08 PM Poster : Maxwell Craven

Normally I would agree, except that quote.com has an extremely reliable network with fast downloads and tons of intraday back data that nobody else can come close to matching. I've already taken the webmaster's suggestion about text files and it works well so far.

On 12/1/2004 1:47:38 PM Maciej wrote:
Its a bit sad when one has to resort to such tactics to "persuade" a data supplier to do the obvious and necessary. Rather than put pressure on Quote.com to change, users should vote with their feet and move to another more profesional data provider.

The more we think about this, the more we think Quote.com and other vendors will follow eSignal and convert all historical QQQ data to QQQQ. If your vendor doesn't add QQQ historical to QQQQ, you should complain, because they should.

On 11/30/2004 3:43:38 PM Ward.net Webmaster wrote:
QQQ is still going to be in some kind of existence as far as we have been able to find out. Quote.com says they will still be sending data for QQQ (we'll see tomorrow!). However, even if QQQ still exists on Quote.com we would expect volume levels to be less as some people switch to QQQQ. So beware if your models depend on volume indicators. Hopefully they will convert historical QQQ data to QQQQ.

eSignal's forum posts indicate they will switch to QQQQ and that they will convert historical data, so we guess they will not have QQQ tomorrow. In that case, you should be able to easily switch from QQQ to QQQQ via add/remove chart pages.

If you want to start using QQQQ and you want to append it to historical QQQ data, you should load QQQ tonight and export a text file of all your data. Then rename the text file QQQQ. Put it in a folder and then Add Directory to that folder in NeuroShell. NeuroShell should blend the two together. However, there will still be volume issues as the QQQQ volume level may be different than the old QQQ levels.

If you go to download historical QQQQ data tomorrow, and it comes, then we should assume the vendors just transferred the QQQ historical dataover. In that case, all you should ahve to do is add/remove chart pages.

If you are using QQQ as Other Instrument Data, you will have to just replace it with QQQQ if QQQ doesn't stay around.

We need an Objective Function that considers intratrade drawdowns
Date :12/3/2004 5:08:19 PM Poster : Brad Stern

Of all the objective functions in the trader available when building a trading strategy, none of them consider intra-trade drawdowns (give back of profits). All that matters is if you lose money from the entry price. If you ride a Parabolic trade up 100% and then have the price go all the back so that the trade closes out with a 1% gain, the objective functions view this as ok as long as the 50% decline in P&L did not occur from your entry point. If any of you think an objective function that considers intratrade drawdown to optomize on is important, please let Steve know. Currently, this is not considered to be desired by a majority of users.

Re: We need an Objective Function that considers intratrade drawdowns
Date :12/4/2004 2:15:21 PM Poster : Steve Eberbach

Brad: I agree almost completely. I have long debated (even with Steve Ward) the need for being able to define objectives of trading.

Recently, I have concluded that really we need even more to set constraints on trading so that the optimization does not waste time looking at possibilities which are impractical, as there are so many. Better, I think, to be able to set limits on an indicator you can write with NST development tools: "Total Intratrade drawdowns". or "median intrattrade drawdown", or "average intratrade drawdown", or "average of worst 10 percent of intraday trade drawdowns", and tell the optimizer to skip the whole calculation and "kill" the candidate if the constraints you choose are violated, or violated "too much", (softer constraint which penalizes the objective function) After all, the objective really is Profit, but other considerations are so unique and there are so many that it would be hard to fit them into even a laundry list of magic objective functions. And it might be too hard for users to learn a whole new art of objective function design. See Google for "Sortino Ratio", for example, and you'll see it's a can of worms.

And better with respect to adding more complexity to NST to simply enable an indicator YOU DEFINE with tools already in NST to constrain the training, I think. Let the optimizer deal with simple objectives, but be able to block the blind alleys where you find them and fix mistakes the objective function is too simple to deal with.

Steve Eberbach

P.S. Given his track record so far, Steve Ward might even be able to figure out a way to optimize your own constraints!

Re: We need an Objective Function that considers intratrade drawdowns
Date :12/5/2004 8:32:32 AM Poster : Steve Ward

Several users have discussed the issue of custom fitness functions with me, but the only debate has been the priority, ie, when not if. True, I don't think it will be a silver bullet, but I do think it will be useful, and is certainly oft requested. However, the things in 5.0, like sending trades to brokers, new types of bars, drawing on the chart, workspaces of several charts, etc are things users and prospects alike request EVERY day. Sometime after these are introduced, I suspect we will get to custom fitness functions, but it won't be easy to build, or we probably would have just tossed it in by now. There are many features being requested, but we have to make priority choices. For example, one user is vehement that we must be able to pass strings to a DLL, and he is quite mad with us that it isn't there yet. I agree with that too, but should that and custom fitness functions be programmed before new bar types and a broker interface? I'm thinking that once 5.0 is out, we need an automatic online voting system so we can see objectively the level of interest in the various feature requests. Contrary to what some of you believe, we don't implement features based on MY trading needs and desires (we only develop add-ons based on that, because add-ons are done by other programmers who normally work on our other non-trading products). So I continue to encourage more of this discussion.

Steve: (and others interested in "fitness" definition)

By debate, I DID mean priority, since this has been an issue for a long time, and back in the days we made a voting wish list, the fitness issue was high on the priority of wishes, but people also realized that the effort required was so great, that when required programmers' time is added into the mix, that cost trumps the "priority" of having a full blown Fitness Wizard.

The biggest reason I suggest using constraints in optimization is because I thought that would be much easier and faster to implement as a first step to making the whole Genetic/Neural optimization package more complete, as it already is in GeneHunter. Easier and faster means sooner. I would rather have a little now, than the whole enchilada someday in the distant future. After all, we gotta walk before we can run.

Secondly, I feel that even simple constraints can solve over 90% (maybe even 200%!) of the job that would be done by writing fancy custom fitnesses. This is evident when you look at Ranier Storn's Differential Evolution page on the internet:

http://www.icsi.berkeley.edu/~storn/code.html

Since the Indicator Wizard is already highly developed in NST, and since GeneHunter is also already embedded in NST, I thought that some integration of what is already programmed could be done quickly, and that once users got ahold of even a rudimentary capability, everyone might be able to explore and discover exactly what, if any, more work needs to be done on custom user programming of fitness.

Additionally, I still believe that simply adding an ability to penalize already existing NST fitnesses (by using the Indicator Wizard to write a "cost" indicator which can be applied to each trade just like a slippage or commission cost, right in the costs dialog box) also could handle (most of) the job that custom fitness functions would do. That suggestion was my way of asking "wouldn't it be easier to accomplish much of the purpose of custom fitnesses without a major rewrite of the whole NST program structure?" That way, a small part of the if and "when" could happen now, rather than someday after all the newer more pressing wishes which keep growing like mushrooms all get finished.

constraints
Date :12/6/2004 10:00:17 AM Poster : Brad Stern

Hi Steve's and thanks for the input.

While constraints to speed optimization would improve the program, there is nothing that looks at daily P/L drawdown from a peak. Therefore, the ability to make custom constraints would not benefit me here.

Steve: (and others interested in "fitness" definition)

By debate, I DID mean priority, since this has been an issue for a long time, and back in the days we made a voting wish list, the fitness issue was high on the priority of wishes, but people also realized that the effort required was so great, that when required programmers' time is added into the mix, that cost trumps the "priority" of having a full blown Fitness Wizard.

The biggest reason I suggest using constraints in optimization is because I thought that would be much easier and faster to implement as a first step to making the whole Genetic/Neural optimization package more complete, as it already is in GeneHunter. Easier and faster means sooner. I would rather have a little now, than the whole enchilada someday in the distant future. After all, we gotta walk before we can run.

Secondly, I feel that even simple constraints can solve over 90% (maybe even 200%!) of the job that would be done by writing fancy custom fitnesses. This is evident when you look at Ranier Storn's Differential Evolution page on the internet:

http://www.icsi.berkeley.edu/~storn/code.html

Since the Indicator Wizard is already highly developed in NST, and since GeneHunter is also already embedded in NST, I thought that some integration of what is already programmed could be done quickly, and that once users got ahold of even a rudimentary capability, everyone might be able to explore and discover exactly what, if any, more work needs to be done on custom user programming of fitness.

Additionally, I still believe that simply adding an ability to penalize already existing NST fitnesses (by using the Indicator Wizard to write a "cost" indicator which can be applied to each trade just like a slippage or commission cost, right in the costs dialog box) also could handle (most of) the job that custom fitness functions would do. That suggestion was my way of asking "wouldn't it be easier to accomplish much of the purpose of custom fitnesses without a major rewrite of the whole NST program structure?" That way, a small part of the if and "when" could happen now, rather than someday after all the newer more pressing wishes which keep growing like mushrooms all get finished.

On 12/5/2004 8:32:32 AM Steve Ward wrote:
Several users have discussed the issue of custom fitness functions with me, but the only debate has been the priority, ie, when not if. True, I don't think it will be a silver bullet, but I do think it will be useful, and is certainly oft requested. However, the things in 5.0, like sending trades to brokers, new types of bars, drawing on the chart, workspaces of several charts, etc are things users and prospects alike request EVERY day. Sometime after these are introduced, I suspect we will get to custom fitness functions, but it won't be easy to build, or we probably would have just tossed it in by now. There are many features being requested, but we have to make priority choices. For example, one user is vehement that we must be able to pass strings to a DLL, and he is quite mad with us that it isn't there yet. I agree with that too, but should that and custom fitness functions be programmed before new bar types and a broker interface? I'm thinking that once 5.0 is out, we need an automatic online voting system so we can see objectively the level of interest in the various feature requests. Contrary to what some of you believe, we don't implement features based on MY trading needs and desires (we only develop add-ons based on that, because add-ons are done by other programmers who normally work on our other non-trading products). So I continue to encourage more of this discussion.

On 12/4/2004 2:15:21 PM Steve Eberbach wrote:
Brad: I agree almost completely. I have long debated (even with Steve Ward) the need for being able to define objectives of trading.

Recently, I have concluded that really we need even more to set constraints on trading so that the optimization does not waste time looking at possibilities which are impractical, as there are so many. Better, I think, to be able to set limits on an indicator you can write with NST development tools: "Total Intratrade drawdowns", or "median intratrade drawdown", or "average intratrade drawdown", or "average of worst 10 percent of intraday trade drawdowns", and tell the optimizer to skip the whole calculation and "kill" the candidate if the constraints you choose are violated, or violated "too much", (softer constraint which penalizes the objective function) After all, the objective really is Profit, but other considerations are so unique and there are so many that it would be hard to fit them into even a laundry list of magic objective functions. And it might be too hard for users to learn a whole new art of objective function design. See Google for "Sortino Ratio", for example, and you'll see it's a can of worms.

And better with respect to adding more complexity to NST to simply enable an indicator YOU DEFINE with tools already in NST to constrain the training, I think. Let the optimizer deal with simple objectives, but be able to block the blind alleys where you find them and fix mistakes the objective function is too simple to deal with.

Steve Eberbach

P.S. Given his track record so far, Steve Ward might even be able to figure out a way to optimize your own constraints!

On 12/3/2004 5:08:19 PM Brad Stern wrote:
Of all the objective functions in the trader available when building a trading strategy, none of them consider intra-trade drawdowns (give back of profits). All that matters is if you lose money from the entry price. If you ride a Parabolic trade up 100% and then have the price go all the back so that the trade closes out with a 1% gain, the objective functions view this as ok as long as the 50% decline in P&L did not occur from your entry point. If any of you think an objective function that considers intratrade drawdown to optomize on is important, please let Steve know. Currently, this is not considered to be desired by a majority of users.

Re: We need an Objective Function that considers intratrade drawdowns

Date :12/6/2004 1:50:21 PM Poster : Ward.net Webmaster

We're certainly willing to entertain more objective functions, but we actually already have a function that considers intra-trade drawdown. It is:

MaximizeReturnOnAccount*EquityCurveCorrelation

If you take a look at an equity curve you will see that it does change intra-trade. Many traders consider a smooth but rising equity curve to represent an optimum system. Our goal with this function was to duplicate what what we felt most traders look for anyway.

Bug in trading systems using Strategy Wizard

Date :12/4/2004 3:01:08 PM Poster : Steve Eberbach

Lately I have been working on feeding signals of one Trading Strategy into another, and getting incorrect results.

Sometimes the Trade by Trade results do not agree with the summaries, and dates and times get scrambled. I have not found a good way to duplicate this for debugging, but I have learned ONE thing to look for to avoid writing bugs into complex strategies.

That is: Trading Strategy Signals occur on the close of the bar preceding the bar of execution. The Wizard does not, however, distinguish when you specify "Long/Short entries exit existing short/long positions, whether the exit should occur on the open or the close of the next bar. If, for example, you use a strategy which enters long or short on the close, and combine with a strategy which exits at market, the first strategy's(A) signals will always tell the second(B) to exit on the open, when you meant to tell it to exit on the close if the exit was signalled from strategy A's position reversal, and at the open if it was from your other exit rules in strategy B.

I thought I made millions on paper this way, only to find that some trades happened in testing before I realistically would have the needed information.

Re: Bug in trading systems using Strategy Wizard

Date :12/5/2004 8:17:15 AM Poster : Ward.net Webmaster

It would be really nice if you could send us the chart next time you see this. We are ready to test a bugfix 4.6 release right now and we could fix it in that release if you get it to us fast enough.

Re: Bug in trading systems using Strategy Wizard

Date :12/5/2004 2:59:22 PM Poster : Steve Eberbach

Steve:

The charts I have seen scrambled dates are huge, and use custom indicators.
I will try to derive something smaller which exhibits date scrambling.

The other issue, a simpler one that I described in my post, ie that using longs or shorts as well as "exit" to exit one strategy causes "exit" signals associated with the reversal strategy to merge with the reversal signals, so there is an uncertainty of one bar's time delay of when that signal should cause execution of a trade when the trade is executed in a second strategy which uses the first strategy' exit signals as a condition.

I think the bug in the trade by trade arises when an exit is requested to occur (on the open) before its associated entry on the close. I could send printouts of the charts and tradebytrade dialogs to illustrate the discrepancy, and maybe use standard rather than custom indicators if you need a complete chart rather than just outputs.

Steve

Fuzzy patterns and Markov Models

Date :12/11/2004 5:18:19 AM Poster : Phil Greenwood

I've recently started exploring Markov Models for pattern recognition, and before starting to taking the plunge and committing lots more time to research (and possibly add-on development), I'm interested in finding out how similar these are with the existing fuzzy pattern add-ons.

Markov Models are used extensively in speech recognition applications, whose time series data are similar in many ways to financial data; patterns may have variable lengths, numbers of segments, amplitudes, noise, segment curves etc. Furthermore, the need for speed is high in speech recognition.

My research stems from a concern that I have with the Fuzzy Pattern add-on, which is that it doesn't allow for time distortion of the pattern...The fuzzy patterns in the add-on have a single setting for segment size - leading to the same number of bars per segment of the pattern. This seems to me to be a weakness, but perhaps this is an intentional design decision, but I would be interested in understanding more about how this decision was made and its rationale...

Thanks for any insight you can provide,
Phil Greenwood

Re: Fuzzy patterns and Markov Models

Date :12/12/2004 7:40:47 AM Poster : Steve Ward

You can always put more flexibility or features in an add-on, especially when you are breaking new technical ground as we have done so many times. We could have also allowed more segments or more than five slope levels. The question becomes when does the additional complexibility increase the likelihood of overfitting? What new features increase the confusion for users without corresponding increase in the probability of better models going forward? For example, instead of a longer segment in the midst of shorter ones, would two adjacent short segments both with the same slope level produce results almost as good? At what point is more juice not worth the squeeze? It's hard to know, so you just stop where it feels right. You can always add more later if you become convinced it's needed.

Gathering Intraday Data-an Inexact Art

Date :12/13/2004 11:47:44 AM Poster : Steve Eberbach

I wish to point out the excellent article in the section entitled "Known Bugs...Warnings"

It is this problem I am wrestling with now, for good reason: The G.A. in NST has pointed out to me (rather convincingly) that the inexactness of data feed timing is the best property I can find so far which generalizes better out of sample than in sample! My theory is that computerized trading tools are being used at a rate increasing faster than the rate of the data vendors' and platform vendors' ability to get the time-sync bugs out. So many people are trading stale data, or are trading data that is not even valid yet and don't even realize it. This creates a statistically powerful opportunity because you know that when you have a fast and steady-delay data feed you know others will react in a statistically valid and repeatable way over a short time interval after your computer has already given its signals!. Did you ever wonder why there are gaps at half hour, ten minute, five minute, and one minute bars????? So we little traders need to simply get our bars in a row, so to speak, and we get several ticks' edge.

One man's ceiling is another man's floor. The glass is not half empty, it's half full. One Trader's Stop is another Trader's Limit.

Anyway, I need to get resolution of this fast-trading timing in the Trading Strategy Wizard soon. It will give NST users an edge. I will get to the bottom of it before the next test release, if I possibly can, even working all-nighters.

Training and Optimizing times

Date :12/16/2004 4:27:45 AM Poster : Spyros Constantinides

Dear Steve Ward,
Well done for a nice product, generally I am happy with neuroshell but I think it needs major improvement.
My models finish training and optimizing roughly in 5 minutes, which I find, unacceptably quick. By definition neural networks and genetic algorithms don't find the best solution but try to come close. So I think the accuracy would improve a lot if the training and optimizing took for example 10 hours. I use daily data. I feel no matter how good neuroshell is I don't think it can find the best model so quickly. I have experimented with all the functions in the program. Is it possible to modify my product for extended training and optimizing? Will you have this feature in new updates?

Re: Training and Optimizing times

Date :12/16/2004 11:06:35 AM Poster : Steve Ward

You'll be glad to know we already have the ability to set the time that optimization takes place. You can shorten it or lengthen it. You can make it 10 hours if you want. You may not have seen it because you may not have turned on all your options yet. Turn them on and then look at the optimization tab. In addition, if you set your neural nets to 80 hidden neurons, they will train even longer because you'll get tighter fits. But for the record, we disagree with the premise that longer is better. Often longer means overfitting. The other thing you have to understand is that you are not dealing with backprop nets, which have a crude and therefore slow training method. If you have used backprop nets before, forget everything you learned and start over - these nets are different!

Re: Training and Optimizing times

Date :12/21/2004 5:19:54 AM Poster : Phil Greenwood

Spyros's message got me thinking: How are the estimates of training and optimizing times calculated? I'm doing an optimization at the moment that it started off estimating to take 6 hours, and it is now estimating three days and change - and it's been running all night. (It's a research oriented, "outcome agnostic" test, rather than a conventional trading system optimization, so the long run is OK).

This behaviour isn't unexpected because some of my parameters turn other parameters on and off, but I'm curious about how I should allow it to set my expectations - presumably in this case it's feasible it could be ready for Valentine's day... or maybe if I'm lucky I get an early Christmas present!

And also, how does the GA / Neural Net know when it's done? I don't recall ever setting such a criteria!

Phil

Re: Training and Optimizing times

Date :1/12/2005 5:19:50 PM Poster : Steve Ward

GAs never know when they are done, because there is no way to know if the "best" solution has been found already or not. You can only decide if the current best is good enough, or if finding better solutions is getting harder. Our GA algorithm just stops if a better solution hasn't been found in so many generations (there's an internal algorithm that estimates that.) That's why we added the ability for you to make it go more or less time. By the way, trailing and other stops greatly increase the time to optimize, because backtesting them is soooo much slower. Anything that estimates 3 days either has stops, or is way too complicated in my opinion. There's a nice tip explaining that called "When optimization is really slow".

High-Frequency Bars

Date :12/23/2004 4:36:37 AM Poster : Allan Kaminsky

My custom trading program uses higher-frequency bars than 1 minute. No, they're not ticks or tick-bars. They're arbitrary time-based bars, such as 6-second bars. And yes, they're not all noise, but good, coherent bars with tremendous, useful detail. Is there, or will there be, any way to do such stuff with NST?

Re: High-Frequency Bars

Date :12/25/2004 5:39:16 PM Poster : JackR

Allan:

I don't believe they are available now, I'm not an NSDT user, just a NST user so they might be available in the Day Trader. However, last summer there was a post in this forum that said:

"In release 5.0 we are currently planning to have N hour, N minute, N second, N tick, and N volume bars ... although some combinations (i.e. 1 tick bar or 100 volume bars, or 1 second bars) will probably be pushing the boundaries of how fast the Trader can evaluate each bar."

Since 5.0 should be out next year sometime it looks as though you'll get what you want then. Of course, planning a feature and delivering it are not the same thing.

Jack

Favorite add-on?

Date :1/9/2005 7:12:59 AM Poster : danno

A question for those who are experienced in using the Trader to make profits:

What add-on(s) have you found most useful in generating accurate, tradable signals???

Danno

Re: Favorite add-on?

Date :1/10/2005 8:50:08 AM Poster : Richard Cohen

I don't have them all because I've only had NSTP about 6 months, but I've done quite well with adp turboprop and fuzzy sets. Sometimes I use them together, usually inputting FS into AT, but you can also use FS to analyze AT or other net outputs. The big key for me was not to optimize all the parameters, just a few. I'll lock in the trainbars, aheadbars, retrain, and sometimes even the hiddens. In the FS I'll lock in the number of sets and the some of the parameters of the indicators I am fuzzifying. Also I like to link parameters of the buying indicators to the symetric ones in the sell rules. Returns aren't as good when you don't optimize as many things, but the results seem to last longer when trading. Let me know if you (or anyone else) find the same.

Signal and Noise step request

Date :1/17/2005 6:14:53 PM Poster : Sunny

I have lately been trying without any success to use NeuroShell DT to separate noise and signal.

I was wondering if anyone who has already done this would mind telling me what tools and steps to follow in order to achieve this.

What inputs should I be using?
What should be the objective function?

Regards,

Sunny

Re: Signal and Noise step request

Date :1/18/2005 11:49:08 AM Poster : Sunny

In particular, I am intersted in using wavelets and Fourier transforms.

Re: Signal and Noise step request

Date :1/18/2005 4:13:52 PM Poster : Bertrand

Hey Sunny,

if you can outline a bit more what project you are trying to accomplish, there can be more specified recommendations.

I had very good success for my applications with the Trader; I use Jurik's MA (& also others) very often to noisefilter all in & outputs before feeding them into any net. This ussually stabilizes the net & reduces the forecast error...

Inputs & objective functions can be the most important thing, so without knowing some more details I think generalizations may only do you worse.

Let me also add that I've had more success with pattern recognizition than pure "forecasting" of some time series.

Best of luck,
Bertrand

Re: Signal and Noise step request

Date :1/19/2005 2:55:18 PM Poster : Sunny

Bertrand,

Thank you for your reply.

I am trying to learn how to use wavelets and fourier transformations to separate noise and signal. This was my original post; however, I forgot to mention the technique I wanted to use to accomplish this. Silly me. :)

On a different subject, I saw that you are using Jurik's tools. Have you used the DDR and WAV tools? What is your experience with them, and how do you use them?

I tried using the DDR; however, I have been having some problems with its use. It is not meeting my needs or expectations. It will only take a limited number of inputs at once.

WAV I have tried using it in a cascading forecast chart at the first cascade level, but because it will only take one input at a time, I am using it together with other indicators at this first stage. I was able to decrease the overall training average error of the prediction, but not by much. This indicator also did not meet my needs or expectations.

In addition, to this I have been trying the checkbox that is supposed to balance the prediction with equal posilve and negative inputs. Have you used this checkbox? What is your experience with it? The checkbox is located under the training tab in prediction parameters. It is supposed to adjust the training set for trending markets by evenly distributing training bars.

It seems to lower my number of winners - losers, it lowers my percentage of correct signs; however, it increases the ratio of gross profit/loss, and it increases the ratio of avg. win/avg loss, and to be honest I am puzzled by this.

Overall, I would say that in the final cascade effect the annual return increases. The whole thing seems counter-intuitive, but it seems to be sort of a trade-off.

Regards,

Sunny

Hey Sunny,

if you can outline a bit more what project you are trying to accomplish, there can be more specified recommendations.

I had very good success for my applications with the Trader; I use Jurik's MA (& also others) very often to noisefilter all in & outputs before feeding them into any net. This ussually stabilizes the net & reduces the forecast error...

Inputs & objective functions can be the most important thing, so without knowing some more details I think generalizations may only do you worse.

Let me also add that I've had more success with pattern recognizition than pure "forecasting" of some time series.

Best of luck,
Bertrand

Re: Signal and Noise step request

Date :1/19/2005 7:36:57 PM Poster : Philippe Lonjoux

Sunny,

Fourier analysis breaks down the price into constituent sinusoids of different periods. I understand the usefulness of this technique when the signal's frequency content is stationary. However, financial time series may exhibit clusters of volatility and non-Gaussian behavior in price jumps making them non-stationary. Accordingly, FFT filtering may not fully capture these characteristics that make up most of the "knowledge" in the series.
In an effort to correct this deficiency, a Short Time Fourier Transform (STFT) could be used by limiting the analysis window to a particular size. The series is then mapped into a two-dimensional function of time and frequency. However again, the window size cannot vary to determine more accurately either time or frequency.

Wavelet analysis, in contrast, uses approximating functions that are localized in both time and frequency space. It is the breaking up of the time series into shifted and scaled versions of an original mother wavelet that can capture some underlying processes (components) that drive the price. I have been somehow successful in using an undecimated Haar wavelet transform that I developed to build a multiscale-based strategy. You may want to use the WaveletFilterHaar Indicator and calculate the residuals to extract some useful components.

Philippe

Re: Signal and Noise step request

Date :1/20/2005 2:24:44 PM Poster : Sunny

Philippe,

Your answer crossed with another post I had just filed probably as you were filing this one.

I agree on the part of stationary data, and I appreciate the insight on the STFT.
This part I did not know as I had been wondering if it could be used for financial data.

In addition, I found out that, in particular, the probability distribution curve for the intra-day data is probably non-Gaussian according to some papers I read. Some of them remarked that a better approximation would be the Poisson distribution.

With regards to wavelets, I am still trying to figure out how to use them from a practical point of view.

If you would not mind sharing this with us, I would be very grateful.

In NSDT there is a collection of wavelets grouped into three different parts:

Coefficients
Coefficients with sorting
Filtering

The wavelets with coefficients have the following parameters:

window exponent
wavelet number

The wavelets with coefficient with sorting have the following parameters:

window exponent
sorted wavelet number

Finally, the wavelets with filtering have the following parameters:

window exponent
percent threshold

I am at a complete loss as to the proper usage of each of the three categories.
I have not yet been able to figure out when is it appropriate to use each of them.

Moreover, I had as I mentioned earlier my original purpose is to attempt to separate noise and signal. How do you determine which of the three categories are presenting you with the signal, and how do you determine which of them present noise?

Sorry, about all the detailed questions; however, I am still at the stage of trying to figure out both the theory and the application portion.

I found the following site which contain some insight from a practical point of view:

http://strule.cs.qub.ac.uk/~fmurtagh/result.html

They mention the use of the Haar à trous wavelet transform. My understanding is that the wavelets in Advanced Indicator Set 2 are also this same kind of wavelet. Apparently, the advantage of this type of wavelet is that it does not interefere with the last data point

A more theoretical document on the same would be the following:

www.unige.ch/fapse/PSY/persons/prof-ana/renaud/papers/NeuroWavelet.pdf

According to them the Haar à trous wavelet transform is non-decimated.
So I am assuming that the Haar à trous wavelet transform in the Advanced Indicator Set 2 meets the description of this paper, but perhaps we could get some confirmation of someone who has worked with it.

Regards and thanks in advance,

Sunny

Re: Signal and Noise step request

Date :1/21/2005 1:50:47 PM Poster : Philippe Lonjoux

Sunny,

Here is a link on a wavelet transform for filtering financial data streams. The paper describes a time-based and redundant Haar a trous wavelet transform that you could use within a Multiscale Entropy Filtering scheme. That should give you some elements as to extract noise from signal.
http://strule.cs.qub.ac.uk/~gzheng/financial-engineering/finpapermay99.html

"Apparently, the advantage of this type of wavelet is that it does not interefere with the last data point"
This is true since the Haar transform is causal (it uses past data only to nowcast). But it comes at the price of a lag which is common to any MA indicators. Usually, neural nets make up for this lag by gaining in generalization.

You can get around this issue anyway, not having any lag and preserving the predictive skills of the transform. Check this paper on Anna Goldenberg's Home Page:

"Time series forecasting using wavelets with predictor-corrector boundary treatment
http://www-2.cs.cmu.edu/~anya/

Hope this helps

Philippe

Philippe,

Thank you for your response and your comments.

The first paper had crossed my path; however, as they mentioned in the paper "Choosing the numbers of input and hidden units is something of a black art,..."
I would extend this in my case for the usage of the wavelets themselves. :)

The second paper seems to be unavailable in the internet.

I will keep you informed if I happen to make any progress with this.

Regards,

Sunny

A couple of observations:

You could do worse than explore John Ehlers' insights about using Hilbert transforms vs. Fourier transforms. His we site goes into this issue at www.mesasoftware.com. His point is simply that Hilbert transforms are quicker (require less data to come to an answer) than Fourier transforms.

Also in his books, Ehlers goes into some depth about filtering techniques...the great thing about his approach is that he doesn't hide anything - it's all there in his books, from theory to including code. Of course rather than converting the code, you'll probably prefer to buy the NS add-on.

And a traditional approach is to use a moving average...and there are many you can choose from from the "800+ indicators". I must stop sounding like a salesman...

Of course there's no universal answer to noise elimination - one theory says that you shouldn't allow the concept of noise, that it's just signal you don't understand! Personally I think it's a useful abstraction.

I know nothing about wavelets, so I can't help there.

Cheers,
Phil

Sunny,

I'm travelling at the moment, but I'll be home in a few days when I can check the books. Here's what I think you're looking for:

Chapter 9_period: This is the period of the dominant cycle which = 1/frequency. I suspect this is the Hilbert transform by another name.

Chapter11_sine: This is the sine of the phase angle of the dominant cycle. So the InvSin of this should get you the phase angle.

His books make these very transparent (though they are quite expensive). I'm pretty sure that the Hilbert transform is presented in both "Rocket Science" and "Cybernetic Analysis".

Phil

Position Sizing Trick?

Date :1/18/2005 11:19:45 PM Poster : stephen

Is there any way to do position sizing when inserting a trading strategy in a Nueroshell chart? I just see three options, fixed number of shares, fixed amount of shares, and bet the current balance.

> ***Re: Position Sizing Trick?***
>
> Date :1/23/2005 2:50:48 PM Poster : Maciej
>
> I'm not sure if the method I use for position sizing will be suitable for you. In any event it's a fairly crude method but it can work. It essentially works by setting up additional trading strategies triggered by a a previous one. Thus if trading strategy#1 is triggered, then trading strategy#2 can be triggered by trading strategy#1 plus any other criteria. This works for pyramiding.
> Its not ideal but one day NSDT perhaps will further enchance the trader's side (money mangement) rather than the intellectual side of the product.

Challenge for programmers

Date :1/19/2005 8:10:39 PM Poster : Sunny

To everyone:

I am not a programmer; however, there is a big gap in NeuroShell with regards to having a standard for inputs.

For instance, I think that everyone agrees that normalizing, N, and detrending, D, the data provides in many cases better results as compared to using raw data.

However, there is a catch. In order to process the raw data through this technique N&D it has to be entered by hand. This mean every high, low, close, open, and volume field has to be entered manually for every choice of N & D.

I have a better idea why couldn't NeuroShell, NS, do this for us.

I would like an initial module that allows the user to choose the data from several different categories, and then NS would spend some time determining which combination of N & D (NS would have a predefined set of N & D formulas to choose from) would provide the smallest error or the highest R-squared or some other statistical measure with regards to a set of indicators (a second set, defined by the user)
which could be used for predicting a future value. No optimization would exist at this stage. This would simply be a quick and dirty set of tests to begin the real work. However, I believe that the time spent at this stage could determine from early on the success or failure of a given strategy.

The advantage of this work is that we would get the following:
1- normalization of the data
2- detrending of the data
3- a match between inputs and a variable to predict
4- a considerable savings in time
5- more robust models

With something like this almost everyone using NS would have at least one or two great predictions with which to work from.

So my challenge is the following:

Is there someone with sufficient programming skills willing to undertake such a project?

I would like to hear from everybody. Perhaps there is someone with a different approach, a different idea, or perhaps a solution.

Regards,

Sunny

I tend to agree with you that this type of ability to improve the inputs would be a useful enchancement to NSDT. Who knows perhaps Steve Ward will take up this challenge.

Normalizing other instrument data
Date :1/20/2005 4:51:48 AM Poster : Phil Greenwood
If you're using other instrument data as an input to a neural net, is it possible (or necessary/advisable) to normalize it?

Thanks,
Phil

Re: Normalizing other instrument data
Date :1/20/2005 9:48:44 AM Poster : Steve Ward
All inputs to all of our nets except the addon Adaptive Net Indicators (ANI) are normalized with respect to each other within the nets already. If you want to do more, it probably won't hurt anything, but I doubt it will help much. None of the nets normalize inputs or outputs with respect to time, which is why it is important to use indicators or use change/percent change instead of raw prices. The only time you might get away with raw prices is when the history was basically at the same price level.

Re: Normalizing other instrument data
Date :1/21/2005 9:33:48 AM Poster : Kermit
Hi Steve,

Is there any way to remove a seasonal tendency from data, or have you given any thought to how this might be done? The method I use is to export the data to a spreadsheet, remove the long term trend (not always easy), and then remove the seasonal as best I can. I am looking for deviations from what should be expected seasonally.

Kermit

PS - Tell Andre that I love the Hodrick-Prescott filter that he programmed when doing things like this.

So if I'm using a price time series as another input to a regular NeuroShell Turboprop neural net, is it advisable to input the log, or deviation from a long term average, of the price to normalize this data against time?

Phil

The log doesn't really do the trick. However, the deviation from an average or an index is certainly a good way to go. Percent deviation will be much better.

Re: Normalizing other instrument data
Date :1/24/2005 5:00:10 PM Poster : Steve Eberbach
I like to use the differences of the logs from one time sample to the next: 100 * (ln(data [0])-ln(data[-1]). Also you can modify the usual percent change by substituting a two point average of the two data points instead of just the latest data point as the basis for what the change is a percentage of. (2 * (end - start) / (end + start)). The advantage of the first (change of logs times 100) is that 50 up means doubling, while 50 down means halving. Both have the desirable property that an average or cumulation of this type of "% change" will not acquire a "bias" or "offset" over time when there is no trend in the original data series. Sometimes this gives better results over long time periods than the usual % change definition. The redefined percent change formula is almost equivalent to the first formula if the percent change is less than 5 %.

Another formula I use is, in NST formula language is:
Mul2(Sub(Ln(Avg(Time Series, AvgPeriods)), Lag(Ln(Time Series),Periods Back)), 100)

This is the difference between the log of an average and the log of a lagged data point times 100. This is a good target to predict into the future. If the lag is zero, it makes a great normalizer of current data. It also has the benefit of no cumulative bias for a sequence of halvings and doublings, but no trend in the original data series. It also means that the size of the short term wiggles does not change the slope of a long term trend in your normalized data. It will not distort the slopes of your regression lines. It is more meaningful when your data is volatile.

Steve Eberbach,

You are great. :)

I tried your difference of logs, and I got great results.

Perhaps you would not mind replying with an exact NS formula for your ideas (counted 3 so far).

If you are ever interested in giving a short course on using NS, you can count me in.

Regards,

Sunny

Correction:
In my last post I forgot to multiply the second formula by one hundred to get percentage points instead of decimal fraction. The multiplier should be 200, not just 2.

Fourier Transform indicator

Date :1/20/2005 5:39:45 AM Poster : Sunny

Does anyone know whether the Fourier Transform indicators included in NeuroShell are the normal Fourier Transform or the Short-Term Fourier Transform?

Why?

To begin, I read several posts of people trying to use them; however, some of them had problems with their use.

After researching a little bit, I found the following (ideas below belong to Robbi Polikar):

The Fourier Transform is not a suitable tool for analyzing non-stationary signals, signals whose frequency constantly changes in time. We can obtain the frequency components of the signals; however, we cannot obtain the times when the frequency components occur.

The Short-Term Fourier Transform, on the other hand, is a function of both time and frequency (unlike FT, which is a function of frequency only).

For a complete version of these idea you may go see them at the following address:

http://users.rowan.edu/~polikar/WAVELETS/WTpart2.html

Re: Fourier Transform indicator

Date :1/24/2005 3:06:05 AM Poster : Phil Greenwood

Looking at your reference, the author seems to make a pretty compelling case for using Wavelet transforms rather than FFTs...read further, parts 3 and 4.

Phil,

You are right.:)

You might want to look at my post of the 18th.

I have been looking at wavelets as a possible solution.

My biggest problem is how to use them. I have located thanks to Phillipe some possible ideas to pursue; however, I am at the very early stages.

Regards,

Sunny

Missing quote.com daily data for 1-14-05

Date :1/21/2005 10:59:46 AM Poster : Ward.net Webmaster

Quote.com's web site said they had an outage 1-13-05 but that any data missing would be replaced by 1-18-05. However, as of today 1-21-05, we have noticed that daily data is missing for 1-14-05 for QQQQ, XOM, and probably other stocks, both in NeuroShell and in Qcharts. SPY was previously missing but they got that corrected. We will let them know about this, but you may want to check to make sure that data missing for Jan 14th does not affect your models. After they get it corrected, you will probably have to use the Manage Files button to delete daily data for any stocks that have missing data, and then reload it. Intraday data looks OK, because daily and intraday are two different data streams.

Optimizer

Date :1/26/2005 1:53:50 PM Poster : Mark B.

Hi, In reviewing a question asked about optimizing times, Mr. Ward responsed that it was possible to set the amount of time the optimizer ran. If it took the GA to find the "best" parameter in 20 minutes, it was possible to set the GA to run for, least say, 180 minutes or 3 hours.

My question, by setting the time are you doing a "brute force" optimizion? In other words, are ALL parameters checked during a preset long optimization?

Re: Optimizer

Date :1/29/2005 12:20:48 PM Poster : Phil Greenwood

Whilst I can't give a definitive answer to this (because I didn't write the code), based on my knowledge of GAs and the things I've understood from using NSDT and learned on the training course, I think the answer is no (but a qualified no).

A genetic algorithm is not the same as an exhaustive search...even if you could have an exhaustive search with continuous values (you can only have an exhaustive search with with discrete values). Putting that issue aside, as you crank-up the amount of time available for processing, because of the mutatation element of GAs workings which randomizes the search a little, you could effectively have done an exhaustive search - but there is no guarantee.

I suspect that the GA in NSDT assumes it's finished if it can't get an improvement to the fitness evaluation within a certain number of generations. The power of the GA is it's speed, not its exhaustiveness...but with the ease of overfitting with financial models, exhaustiveness is really not the game, so it's not such a big deal. In my experience, the NSDT GA is a pretty good compromise, and for the most part, it is more than sufficient.

Phil

Hi, In reviewing a question asked about optimizing times, Mr. Ward responsed that it was possible to set the amount of time the optimizer ran. If it took the GA to find the "best" parameter in 20 minutes, it was possible to set the GA to run for, least say, 180 minutes or 3 hours.

My question, by setting the time are you doing a "brute force" optimizion? In other words, are ALL parameters checked during a preset long optimization?

Automated trading?

Date :1/27/2005 5:49:34 PM Poster : Charlie

Hi,
there seem to be a few threads regarding automated trading in this forum, but no clear answers as to how this might be achieved. I am interested in automating signals from Neuroshell so that forex trades are automatically placed at FXCM, or some other forex broker.
Has anyone else ever successfully achieved this?

thanks

Don't know if you are a new user or not, but the October Ward Systems' newsletter said:

First, we have built the long-promised brokerage interface. This is an API that allows a programmer to interface NeuroShell with a brokerage that also offers an API. We will offer at least one completed brokerage interface with release 5.0 as well as a simple example.

Now, if they release 5.0 next month (my prediction based on a very complicated net) you'll have what you want, at least with whatever firm Ward did the initial development with. Based on the extract of the newsletter above, I assume that any broker with an API (interface) to the outside world would be programmable.

You could always try to use Data Exchange API and program a macro to interface with the trading platform that you use. You will need this add-on anyway in order to stream information elsewhere. You can try TradeBolt, it might be able to interface with Neuroshell via the API add-on. I'm in the process of looking into this myself.

Tradebolt is an interesting concept because one interface supposedly connects to many brokers. They claim they have an alternate simplified interface that only takes a line or two of coding. However, currently all of their brokers are futures brokers. As soon as they have some forex and equity brokers as well we may take a harder look at them.

Regarding TradeBolt & use of shortterm systems with lmt orders

basically it is really hard & sometimes stressful to get TradeBolt & the strategy back in sync when there was a problem with the fill & if that real world fill then differs from the expected one. TradeBolt advises their clients to just fire a mkt order if the strategy reports a fill. But guess what if you use it for scalping like systems it prodcues much slippage & oftentimes systems get untradable due to this problem. So please be aware of that in your judgement...or include extra slip in the GA costs to make sure such real world scenarios do not matter too much.

good day

A feature - would you like it?

Date :2/8/2005 2:28:34 PM Poster : Mark B.

One feature that I would like is when running a Prediction or Trading Strategy after, let us say, 5 improvements NeuroShell then produce either the walkforward tests or paper trading test - for each additional improvement.

It's a pain to see good results and then stop optimizing to view the walkforward tests or paper trading test and then start the optimization over again.

I know that I could start the optimization from the last settings, but my understanding is that the GA then goes off in other directions and does not continue in the same direction as it would if the optimization is started over.

Would anyone else like this feature?

Re: A feature - would you like it?

Date :2/9/2005 11:41:55 AM Poster : Steve Eberbach

What I have done to implement "go-back" to partially optimized charts is to stop training on every improvement (after improvements slow down a bit) and save the whole chart with a numbered suffix. This wastes lots of memory, but blank CDRs of DVDRs are really cheap, and saving a chart happens very fast. Later, you can go back and open the charts with lots of out-of-sample fresh data and explore any potential good models you missed during the original training. To me this is essential for success.

Maybe what needs to be saved is a log which allows reconstruction of several sub-optimal models which later are tested and ranked on newer data. Like Billboard top 40, what's the rising star, and what's has-been.

That is a good idea. Time consuming. And you would have to be watching the computer for each improvement. The problem would be if you missed an improvement that could have yielded a great result. An additional thought would be, what if you saved the chart as you described and then let the GA go off in a new direction by picking the last settings - I'm thinkin' myself into a nightmare :) saved charts everywhere! I do like your idea and will start using it.

Given your idea - Neuroshell could (hint, hint) save SubResultsFiles just as you are doing, and then give you a summary of results based on the last, let's say, 5 or 10 improvements. I, like many, have gotten great walkforwards and paper trading results by stopping the GA early. Maybe the good folks at Ward Systems will add this to the "Wish List".

Yes, that sounds interesting. And even a step farther - display the best nets found together and watch them in real time. I have always liked the ability in NeuroShell 2 to make several nets by simply varying the data selection and look at them in real time when trading. This not only gives me the consensus prediction, but it also gives me some indication of the stability of the nets over the training data. This is extremely important to me when betting money on a prediction - how consistent are the nets over the data. When the individual nets are scattered in their predictions, I have much less confidence than when they all come together.

I sense that what most of you on this thread really want to get at is the solution that works best into the future, rather than the one that optimizes best in the past. That is appropriate. Until we have a well programmed way to let you see and cherry pick ALL solutions, I'd suggest that you consider the method documented in the tip called Using Generalize on Optimal Walkforwards. That method will be expanded and simplified in 5.0.

Of course I want the solution which works best into the future. I also want to be the judge of what is "best" in the future. (Bill Clinton would also want to be the judge of what "is" means, but I am not that fussy)

Until we have more good ways to constrain the search space so that a single fitness criterion, such as total profit over time T1 in sample and T2 out of sample, is allowed to be (or constrained to be) sub-optimal to enable several criteria to be optimized simultaneously (particularly at some time interval T2 after training), nothing will beat the human cherry picker. NST is now a very good cherry tree that chooses one nice cherry for you at a time.

If YOU want to CHOOSE your cherries you still have to pick the cherries yourself.

By generalizing Walkforwards with Constraints and Definable Fitnesses.....maybe you could construct a pretty good robotic cherry picker. I think Genehunter is a pretty well programmed way to do these things. While it cannot see and cherry pick ALL solutions, it should be faster than a human at seeing and finding many well-chosen solutions from which to finally choose the "best" ones to trade with.

I'll try to describe the way I like to do this as best as I can and hopefully you can offer suggestions, and it might help in thinking about the Trader. Remember, I'm not the most sophisticated Trader user. (g)

When I use NS2, I build GRNN nets - I am guessing GRNN nets fit the way I build my inputs best, but I'm not sure. I'll build several nets with the same inputs - usually eight nets - varying only the data selection for the trn and tst sets. I simply give it different random number seeds to start when choosing the trn and tst sets. I would like to be able to control how big the "chunks" of data are also. After building eight or so different data sets this way, each under a different filename, I'll run the eight GRNN nets and save them. I then use the "External calls" feature in the Trader to import these, and I can watch all eight nets in one window running in real time. When the eight nets are not well correllated, even if only one or two nets are off by themselves, I do not trust the prediction too much, but if all the lines come together, I assume that the patterns found in the historical data are pretty consistent through time. This can be important when the average of the nets is close to zero, as then a short term swing trading system can be more confidently used - if the nets aren't diverging much. BTW, the GRNN nets in NS Predictor always seem to be very close to an average of the eight nets in NS2. I don't know how practical it would be to build something like this into the Trader, but I do know that looking at both the average of eight nets along with the correlation of those nets gives me much more confidence in making bets in the market. Having a way to look at the confidence of the prediction is equally as important as getting a prediction - for me. And IMHO, having something like this in the Trader would make a great product even better.

BTW, I had the head of the Merrill Lynch office over for dinner last night (we fish together), and his jaw pretty much dropped open and stayed open for hours when I showed him some of the things the Trader would do so easily. He is going hunting for data next week, I think. I don't think too much about what a great product this is until I sit down with someone and demonstrate it.

What is the difference between the Fuzzy Sets and Fuzzy Pattern Recognizer Add-on?

Date :2/13/2005 9:23:08 PM Poster : George

Neuroshell website says:

"The new Fuzzy Sets add-on is somewhat different in that it allows users to describe a combination of values of traditional indicators with fuzzy logic".

that means you cannot use indicators in the Fuzzy Pattern Recognizer ?
only prices...?
If somebody would be able to explain to me the differences and in which way these two add-ons overlap that would be great.

> ***Re: What is the difference between the Fuzzy Sets and Fuzzy Pattern Recognizer Add-on?***

> No, you can apply Fuzzy Pattern Recognizer (FPR) to indicators just as Fuzzy Sets (FS) does. The best way we have thought of to describe the differences is this: Think of the FPR as looking at a time series and evaluating movement of that series over recent time. Think of FS as looking at discrete values in time and evaluating those values with respect to a historical range of those values. E.g.:
>
> FPR - the time series went up, then down, then down sharply.

Custom indicator- please help

Date :2/15/2005 4:22:08 PM Poster : Dov G.

I am attempting to create a custom indicator with a calculation that starts out using a certain formula for the first few bars (until it has calculated five readings) and then changes to something else that uses lagged values of itself as an input after five bars have elapsed.

Would somebody please help? I know in TS one would incoporate a conditional that depends upon the bar count, but I can't seem to figure out how to accomplish a similar thing in NST.

Thank you!

That's because the Prediction Wizard can't get at previous values of something it is building, and some other internal constraints. However, code in C or BASIC can easily do that, just as Easy Code can.

DLL Indictors With More Than One Output?

Date :2/18/2005 2:13:55 PM Poster : Jim Hamilton

I am attepting to convert a DLL that I current run on my CQG system. The main DLL function has 10 inputs and 4 outputs. The output are all passed by array. It appears that NSDT will only allow one output from a DLL indicator. Does anyone know if this is correct? Or did I read it wrong?

Thanks

> Date :2/19/2005 5:01:45 PM Poster : Ward.net Webmaster
>
> You are correct, only one output. However, there's a pretty simple solution. Make another parameter (input) for the DLL function called Mode which takes values 1,2,3 and 4. Send out the output that corresponds with the Mode. Then when you put the indicator in the chart with Mode=1, just copy and paste it three times. Change the Mode to 2,3 and 4 on the new pasted copies. Now you have all four outputs having done little more work than inserted the first indicator. The increase in CPU time should be negligible unless you have a pretty intense set of calculations.

change in order of input produces different output results

Date :2/20/2005 4:42:18 PM Poster : sk

Hi,

when I use the same set of inputs but change the order of the inputs in the input section I get totally different output results. Can anybody help?

Thanks.

sk

Interesting results - pass on technique

Date :3/3/2005 2:03:10 PM Poster : Mark B.

Hi, I got some unexpected results - great results - with a so so trading strategy and got to thinkin' maybe the Neuroshell "Family" might like to know about it.

You either let the GA do it's thing or, as in my case, force the GA into directions it would not normally take in an effort to find unexpected results. (I would sure like a brute force optmizer option outputed to a file that can be loaded in Excel.)

First, I begin by optimizing on "Max Return on Account" (default) and set longest trade to 25 bars. Plus I set "Paper Trading" to 1 year. I want 70 Percent or more profitable trades.

After the less than great results were produced I went back to: Costs >Margin%per share and set it at 500%. Just screwin' around. Ran the strategy and let the GA do it's thing. Got really, really bad results. Really bad percent of profitable trades and a low return.

I then went back to Costs ----->Margin% per share and clicked it off. Rerun the strategy and Picked Yes to use the same optimal settings. Then clicked on "Stop Optimizing" and the results were Great! That the short version.

In long version I stepped back the Margin% by 100% --- 500% than 400% than 300%.....

Each time checking the results.

I hope you find this helpful.

Re: Interesting results - pass on techique

Date :3/9/2005 11:26:46 AM Poster : Steve Eberbach

This is quite interesting to me. I believe that with such low transaction costs these days, the Time Value of Money cost is becoming the most important cost of being in a trade.

I think that setting the interest rate on margin higher should do a similar thing for you, since the Genetic algorithm would have to also consider the time cost more in addition to the transaction and slippage cost. More value would be placed on "stepping aside", which would also reduce exposure to unexpected-event drawdowns, even if total profit was caused to drop a little, compared to being always in the market.

I have a question for Ward Systems: What IS the interest rate on the margin when you are in the trade? I do not see any entry on the costs dialog for setting that cost for borrowing the margin money in percent per year.

Could you add a setting to adjust this cost of margin money while you are invested in a trade? (either long or short). Thanks!

Stocks and Commodities Magazine Tips and Trading Strategy Walk Forward

Date :3/9/2005 10:45:43 AM Poster : Steve Eberbach

The recent bonus issue (2005) has an article by M.H.Pee called "Trend Continuation Factor".

Would somebody be so kind as to post the "tip" for this article/indicator in the tips and trading strategies page on this website? I think many users would give many thanks!

Re: Stocks and Commodities Magazine Tips and Trading Strategy Walk Forward

Date :3/9/2005 7:31:28 PM Poster : Jack Robson

Here is an extract from the S&C magazine public website:

To create the trend continuation factor indicators, select "New Indicator " from the Insert menu and use the Indicator Wizard to create each of the following:

+CHANGE:
CumulativePositiveMomentum(Close,1,1)

-CHANGE:
AbsoluteValue(CumulativeNegativeMomentum(Close,1,1)

+CF:
ConsecutiveSum (+CHANGE, A>B(+CHANGE, 0))

-CR:
ConsecutiveSum (-CHANGE, A>B(-CHANGE, 0))

+TCF:
Subtract (Sum (+CHANGE, 35), Sum (-CF, 35)

-TCF:
Subtract (Sum (-CHANGE, 35), Sum (+CF, 35)

Note: The ConsecutiveSum indicator is a custom indicator that users of NeuroShell Trader can download from the Tips & Techniques section of the NeuroShell Trader free technical support website. It is based on the following indicator with the Xs mapped to one parameter and the numeric parameters hidden:

Sub (CumulativeSum (X,0), SelectiveMovAvg(CumulativeSum(X,0), Not(CONDITION), 1)

To recreate the trend continuation factor trading system, select "New Trading Strategy" from the Insert menu and enter the following long and short entry conditions in the appropriate locations of the Trading Strategy Wizard:

Generate a buy long MARKET order if ALL of the following are true:
A>B (+TCF, 0)

Generate a sell short MARKET order if ALL of the following are true:
A<B (-TCF, 0)

If you have the NeuroShell Trader Professional, you can also choose whether or not the system parameters should be optimized. After backtesting the trading strategy, use the "Detailed Analysis" button to view the backtest and trade-by-trade statistics for the trend continuation factor system.
Users of NeuroShell Trader can go to the STOCKS & COMMODITIES section of the NeuroShell Trader free technical support website to download the sample chart that includes the ConsecutiveSum indicator, +Tcf indicator, -Tcf indicator, and trend continuation factor trading systems

Missing Quote.com data

Date :3/14/2005 4:58:17 PM Poster : Ward.net Webmaster

We have found that Quote.com is missing intraday data from Feb 2002 to May 2002. We have reported this to them, but nothing has changed as of 3-14-05. So now we're asking all Quote.com users to let them know too. But first, load some stock you haven't loaded before back to the beginning of 2002 and verify there is a big gap from Feb to May. Two candidates are SPY and MSFT. We suppose the problem may be on only a few of their servers, which may be why they haven't verified it themselves, so try to note which server you got onto.

Use of Trader to model non-trading problems

Date :3/16/2005 5:20:02 PM Poster : Edwards

Came across this in one of the other forums (but cannot respond to it there) and found use of Trader for other problems intriguing. Has anyone picked this up and could give further guidance on how to go about doing what is suggested here.

Is anyone else using NST as a more general tool?

Discussion Group: NeuroShell Predictor/Classifier/Run-Time

[Discussion Groups | Contents | Post new article | Reply to this article | Search]
From: John Skulavik
Date: October 18, 2004
Subject: Predicting Lotto Numbers
Frank B,

I have been analizing this since 1986. During the 1990's I began using NeuroShell2, the predictor and classifier and now I have found a way to use the Trader Pro and it's complex indicators. First of all you'll never get results from looking at the numbers historically listed using simple neural nets. Secondly you are using far too much historical data. I not going to tell you what I have learned in detail, it took far too long to work it out. However two clues: You need not look back further then about 40 to 80 lottery darws and you build your nets based on areas where the numbers came from in games past. Always incrementing foward and using numbers from games back to build a very wide net with "One Output" that you want to predict. So if it's a three number lottery you'll need three nets about 40 to 80 games deep based on where the numbers come from the greatest percentage of the time. Now don't expect to hit all three numbers anytime. Use these as key numbers played over a few new lottery draws. Before long you'll get the hang of it.
Remember nothing is random everything has a pattern and the patterns change somewhat with time. It's only the magnitude of the problems that make them more difficult to predict. The neural nets of the future, especially with the new 64 bit computers, will change "the die in the wool believers" in classical statistics as the only credible solution to making viable predictions.

SelectiveMax - function output as period ?

Date :4/1/2005 11:58:32 AM Poster : chachi

Would like to leverage SelectiveMax (or similar) and pass it a function output for the windowsize/period (BarsActive or similar) ... how could this be done ?

Trend Trigger Factor

Date :4/8/2005 8:32:56 AM Poster : Sunny

I have been trying to duplicate the results that I am getting in forex with the Trend Trigger Factor on Metatrader. This is a free software. So any of you can try it.

I have included a chart, and in addition I am including the code. The code is broken into two parts. The Trend Trigger Modified, and the ttf Crossings. You would need to install both of these as MetaTrader 3.85 indicators.

I have sent an e-mail to Ward Systems with a picture of the results that I am getting in MetaTrader, and in addition, I have included the indicators for MetaTrader 3.85 (be aware that there is a newer version 4.0; however, these indicators will not work in 4.0)

Editor : The files related to this post can be downloaded from here.

We also also included the Trend Trigger indicator in the Stocks and Commodities section of this site.

Here is the deal. If any of you are good at programming, would you mind trying to copy the code into NeuroShell. Take a look at the charts I have included, so that you can get a feel for the potential of the indicators.

Regards,

Sunny

Re: Trend Trigger Factor

Date :4/10/2005 10:09:53 AM Poster : Sunny

By the way, there are something like 3 or four different versions of the Trend Trigger Factor on the Yahoo groups; however, if you take the time to chart all of them in one page, then you will see that there are some small differences between them.

If you compare them to the price on the chart, then you will see that some of them have a lag in relation to the price graph.

The point is that not all of the variations produce the results that you see on the charts.
The small differences in code between the variants of the same indicator make a huge difference in the final result.

Regards,

Sunny

PS I have sent the other files to Ward to post them later with this thread.

By the way, Ward you are as big as I thought you were for allowing us to share this information between us here at your site. I hope the final result of all of this effort will be the completion of a "good" Trend Trigger Factor indicator and ttfCrossing indicator for NeuroShell. I hope this will be one of those indicators that produce good results for everybody.

Trend Trigger Factor

Date :4/8/2005 8:42:35 AM Poster : Sunny

I have included a chart of Euro and CHF vs USD, and files for Metatrader containing Trend Trigger Factor, ttfCrossings, and iMath.

Regards,

Sunny

The files referenced in this post can be downloaded using the following link:

ttf2.zip

Trend Trigger Factor

Date :4/10/2005 10:27:53 AM Poster : Sunny

Here is an analysis of the differences between the different versions of the Trend Trigger Factor. I hope someone will find it useful. The analysis unfortunately is not mine. It belongs to a very bright chap by the name of David W Honeywell who posts ocassionally at the MetaTrader group in Yahoo.

My only wih is that if you do find it useful that you share your insight (and hopefully modifications to the Stock and Commodity Trend Trigger Factor indicator) with us.

Regards,

Sunny

The difference is

Mikesbon's

```
Inputs:
TTFbars(12),
//12=default number of bars for computation

t3_period(6),

b(1.618),

HighestHighRecent=High[Highest(MODE_HIGH,shift ,TTFbars)];
HighestHighOlder =High[Highest(MODE_HIGH,shift+TTFbars,TTFbars)];
LowestLowRecent =Low [Lowest (MODE_LOW ,shift ,TTFbars)];
LowestLowOlder =Low [Lowest (MODE_LOW ,shift+TTFbars,TTFbars)];
```

Modified v_3

```
Input: TTFbars(15); //15=default number of bars for computation.
Input: t3_period(5);
Input: b(0.7)

HighestHighRecent = High[Highest(MODE_HIGH,shift,TTFbars)];
HighestHighOlder = High[Highest(MODE_HIGH,shift + TTFbars,TTFbars)];
LowestLowRecent = Low [Lowest(MODE_LOW,shift,TTFbars)];
LowestLowOlder = Low [Lowest(MODE_LOW,shift+TTFbars,TTFbars)];
```

Nicks fixed version that is "Reliable"

```
Inputs:
TTFbars(15),
```

//15=default number of bars for computation

t3_period(5),

b(0.7),

Here is the BIG difference

HighestHighRecent=High[Highest(MODE_HIGH,shift+TTFbars-1,TTFbars)];
HighestHighOlder =High[Highest(MODE_HIGH,shift+TTFbars*2-1,TTFbars)];
LowestLowRecent =Low [Lowest (MODE_LOW ,shift+TTFbars-1,TTFbars)];
LowestLowOlder =Low [Lowest (MODE_LOW ,shift+TTFbars*2-1,TTFbars)];

If you look in the dictionary you will see the syntax calls for a starting point for the
Highest-Mode-High and it also calls for how many bars from the start point forward to carry out the calculation .

In the modified versions the highest high recent and lowest low recent do NOT have any bars to calculate .

With no bars to calculate there is no way of making an indicator read properly , that is what is being called "looking into the future" , it can't , that is why it re-calculates and changes .

The right code is Nicks Fix OR the fixed version of the original indicator as posted by Paul Y Shimada .
The original does not have the t3 modification.

Pattern Recognition

Date :4/23/2005 4:17:39 PM Poster : aaapers

Since Steve Ward suggested that we ask for assistance for NST add-ons, I am would like to bring up a an issue regarding the pattern Recognition add-on. I have seen other commercial programs refer to their ability to use Elliot Wave concepts in trading. One program in particular uses the ABC preliminary wave patterns to project entry and exit points. On the surface it would appear that the pattern recognition add-on should easily accomplish the same goal and more. However, in practice I have not been able to do so. Part of the problem is the way the add-on is structured to respond to rises and falls only. However, there are other variables that are required to identify a Elliott Wave initial pattern. For instance in a three segment pattern, segment 2 should not exceed the length of segment 1. Segment 2 should also not extend below the origin of segment 1 if the pattern is an upward moving pattern. As the add-on is structured, I know of no way to acheive this level of recognition. Certainly if there were other programming variables added which would allow for more constraints, this ABC pattern and multiple other patterns would be possible. If someone has a work around for this problem, I would be very happy to hear about it.

> I think I would approach this pattern recognition problem not with the Fuzzy Pattern Recognizer (FPR), but with the Fuzzy Sets (FS) addon. Think of the latter as the building blocks of the former, even though that isn't how we built them. You make you segments first, either with momentum across several bars, or with the regression slope through several bars. That way, you can make the segments any size you want. Use the save indicators feature with parameters hidden from user if you don't want the optimizer messing with segment sizes later (although you may not want to use the optimizer at all). Use FS to get these segments going in the directions you desire - fuzzily. Since you made the segments yourself, you can do various tests on them, like segment 2 not below segment 1, with the regular NeuroShell indicators.
>
> I suppose you could also use FPR if you let if find the segments first, then use the regular indicators to do other tests. But using FS you will probably have more control.

channel

Date :5/3/2005 7:22:01 AM Poster : Seth Nelson-Levy

Does NST contain price channel indicators besides standard deviation ones like BB? I want to use a straight channel or envelope and I cannot find one among the idicators.
Thank you.
Seth

Least Square Moving Average

Date :5/12/2005 1:11:21 PM Poster : John Gotwals

I want to construct a Least Square Moving Average indicator where
LSMA = Endpoint of Regression Line including current bar and previous n-1

Using NeuroShell indicators I have come up with
LSMA(25) = Lag(LinTimeReg PredValue(Close,25,1),1)

Is there a simpler way to generate this indicator in NeuroShell?

Next Day High, Low, Close prediction

Date :5/17/2005 11:44:42 AM Poster : EllisWyatt

Hello all.

What is a good way to construct a Next Day High, Low, Close prediction for, say, EUR/USD in the forex market?

Anyone done this or something similar?

> ***Re: Next Day High, Low, Close prediction***

ESignal 7.9

Date :5/19/2005 7:13:03 AM Poster : The latest version of Esignal (7.9) allows:

The latest version of Esignal (7.9) allows:
a) variations of their continous futures contracts
b) creation of a user's own symbols (ie spreads and such like).

Has anyone tried to retrieve these special types, (user defined), of symbols within NSDT?

> ***Re: ESignal 7.9***

Date :5/19/2005 9:57:20 AM Poster : EllisWyatt

I tried... I don't believe you can directly import a user defined symbol via NeuroShell's "Add New eSignal Ticker Symbol" function.

However, you could use eSignal's Tools | Data Export... function to export a CSV (comma delimited) of your user defined symbol.

Another user had informed us of the continuous futures symbols and how they did not appear to work in the Trader. We have our programmers looking into this to see if it is possible.

We were not made aware of the custom symbols, but certainly we will have our programmers take a look. However, in the mean time, you can always create custom symbols in the Trader. Here is the appropriate help file section:

Neuroshell Trader allows the use of combination ticker symbols which are simple combinations of other ticker symbol prices. When used in a chart, the combination ticker symbol is the primary data series, predictions and trading strategy are based on the ticker symbol combination and all trading statistics are calculated on the combination ticker symbol.

An example of a combination ticker symbol combination might be [5*YHOO-2.5*INTC+3*MSFT], which would result in a price stream on the chart that is 5*YHOO's price minus 2.5*INTC's price plus 3*MSFT's price. Examples of valid combination ticker symbols are as follows:

[YHOO - INTC]
[5 * YHOO - 2.5 * INTC]
[5 * YHOO - 2.5 * INTC + 3 * MSFT]
[YHOO / INTC]
[2 * YHOO / 3 * INTC]

It should be noted that combination ticker symbols are a useful method of creating hedging trading strategies. When using a ticker symbol like [5*YHOO – 3*INTC], long positions would be equivalent to being long 5 shares of YHOO and short 3 shares of INTC. Conversely, short positions would be equivalent to being short 5 shares of YHOO and long 3 shares of INTC.

To create a combination ticker, simply create a new ticker symbol like [5*YHOO-2.5*INTC+3*MSFT]. To add a new ticker symbol, use the add ticker button found in the chart wizard when using Quote.com or eSignal.

I use the following continuous symbols all the time with no problem on 1, 5 and 15 minute bars. Try them. If you can't get these at least, are you sure you are subscribed properly to the exchange that sells them (the ones below are CME)? If you typed these symbols in yourself, I recall you have to use caps and type them exactly as below.

ES #F
ES #F=2
NQ #F
NQ #F=2

I have also used the #F=1 in the past with no problem.

Effectively NSDT can handle combination symbols but what's really useful is that the continous futures symbols can be tweaked to represent better what happens in reality. So a futures symbol SP #F=1 or 2 can be totally requantified to join the contracts in a more useful manner. The tutorial on this from Esignal shows some really useful methods. It certainly would be helpful to be able to use these "adapted" continous futures within NSDT. An example is the problem of using volume with continous futures - by changing the moment when the links between one contract and another is made then the volume values are much smoother rather than the current examples that generally show much lower volumes on contract change.

Our programmers have concluded that these features relating to futures and custom symbols exist only in the eSignal charting package. Since the NeuroShell Trader receives data from the Data Manager and not the charting package, these features are not going to be available in the Trader until eSignal comes out with a new developers API that includes support for it.

[2 * YHOO / 3 * INTC]

It should be noted that combination ticker symbols are a useful method of creating hedging trading strategies. When using a ticker symbol like [5*YHOO – 3*INTC], long positions would be equivalent to being long 5 shares of YHOO and short 3 shares of INTC. Conversely, short positions would be equivalent to being short 5 shares of YHOO and long 3 shares of INTC.

To create a combination ticker, simply create a new ticker symbol like [5*YHOO-2.5*INTC+3*MSFT]. To add a new ticker symbol, use the add ticker button found in the chart wizard when using Quote.com or eSignal.

The latest version of Esignal (7.9) allows:
a) variations of their continous futures contracts
b) creation of a user's own symbols (ie spreads and such like).

Has anyone tried to retrieve these special types, (user defined), of symbols within NSDT?

Re: ESignal 7.9

Date :6/10/2005 2:06:39 PM Poster : Ward.net Webmaster

Some of our users are upset that eSignal has chosen to create continuous contracts in their charting package instead of providing them as symbols that other software can read. We urge you to call or email your complaints to them in large numbers - that is the only thing they will understand.

On 5/24/2005 10:56:10 AM Ward.net Webmaster wrote:
Our programmers have concluded that these features relating to futures and custom symbols exist only in the eSignal charting package. Since the NeuroShell Trader receives data from the Data Manager and not the charting package, these features are not going to be available in the Trader until eSignal comes out with a new developers API that includes support for it.

On 5/21/2005 2:03:49 PM Maciej wrote:
Effectively NSDT can handle combination symbols but what's really useful is that the continous futures symbols can be tweaked to represent better what happens in reality. So a futures symbol SP #F=1 or 2 can be totally requantified to join the contracts in a more useful manner. The tutorial on this from Esignal shows some really useful methods. It certainly would be helpful to be able to use these "adapted" continous futures within NSDT. An example is the problem of using volume with continous futures - by changing the moment when the links between one contract and another is made then the volume values are much smoother rather than the current examples that generally show much lower volumes on contract change.

On 5/20/2005 8:34:00 AM Maxwell Craven wrote:
I use the following continuous symbols all the time with no problem on 1, 5 and 15 minute bars. Try them. If you can't get these at least, are you sure you are subscribed properly to the exchange that sells them (the ones below are CME)? If you typed these symbols in yourself, I recall you have to use caps and type them exactly as below.

ES #F
ES #F=2
NQ #F
NQ #F=2

I have also used the #F=1 in the past with no problem.

On 5/19/2005 4:43:27 PM EllisWyatt wrote:
Continuous contracts...for example, YM #F.... work for me for Daily and Weekly bars....but not for minute bars.

On 5/19/2005 3:36:32 PM Ward.net Webmaster wrote:
Another user had informed us of the continuous futures symbols and how they did not appear to work in the Trader. We have our programmers looking into this to see if it is possible.

We were not made aware of the custom symbols, but certainly we will have our programmers take a look. However, in the mean time, you can always create custom symbols in the Trader. Here is the appropriate help file section:

Neuroshell Trader allows the use of combination ticker symbols which are simple combinations of other ticker symbol prices. When used in a chart, the combination ticker symbol is the primary data series, predictions and trading strategy are based on the ticker symbol combination and all trading statistics are calculated on the combination ticker symbol.

An example of a combination ticker symbol combination might be [5*YHOO-2.5*INTC+3*MSFT], which would result in a price stream on the chart that is 5*YHOO's price minus 2.5*INTC's price plus 3*MSFT's price. Examples of valid combination ticker symbols are as follows:

[YHOO - INTC]
[5 * YHOO - 2.5 * INTC]
[5 * YHOO - 2.5 * INTC + 3 * MSFT]
[YHOO / INTC]
[2 * YHOO / 3 * INTC]

It should be noted that combination ticker symbols are a useful method of creating hedging trading strategies. When using a ticker symbol like [5*YHOO – 3*INTC], long positions would be equivalent to being long 5 shares of YHOO and short 3 shares of INTC. Conversely, short positions would be equivalent to being short 5 shares of YHOO and long 3 shares of INTC.

To create a combination ticker, simply create a new ticker symbol like [5*YHOO-2.5*INTC+3*MSFT]. To add a new ticker symbol, use the add ticker button found in the chart wizard when using Quote.com or eSignal.

Yes. I have . Whilst it works admirably under ES, it does not seem to work with anything else - neither NST , Dynaloader nor Globalserver 2000.. The latter is particularly puzzling in the overall framework since one can convince the GS to collect AB #F when the original quarterly symbol is not even listed. I suspect it is the exclamation mark which is the culprit. Ward are looking into it I understand but this requires help from ESignal, I would guess.

Automation Error in NSDayTraderPro 4.7

Date :6/1/2005 9:36:09 PM Poster : DentalFive

I have written a dll in C++ to calcualte the Wilders Parabolic SAR. When I try to insert a new indicator using the dll I get the following error

Automation Error
The Object Invoked has disconnected from its clients.

This even occurs in the Debugger for Visual Studio when I run NSDayTrader4.7 in the Studio and set a breakpoint in the dll. I can trace through the dll until I get ready to return the array of calculated floats and suddenly the error is thrown. Does anyone know why this is happening and how I can prevent it??

Re: Automation Error in NSDayTraderPro 4.7

Date :6/2/2005 9:41:35 AM Poster : Xprogrammer

Sorry I haven't been participating in the forum for a while, I've had some heart problems. Don't worry, old programmers never die, they just lose their memory. After that they byte the dust.

Anyway, it sure sounds like one of two things:
1. Your output array isn't the same type as NST is expecting
2. You are putting data in the output array outside the bounds of the array. That would clobber NST. Make sure you are starting at the beginning of the array(make sure your index is right), and not putting in more than you should (look at the count).

Re: Automation Error in NSDayTraderPro 4.7

Date :6/9/2005 4:25:27 AM Poster : chachi

Could be a ByRef/ByVal mismatch on the parameters or an Integer/Single/Double type mismatch on the datatype.

Not enough detail given to know for sure unfortunately.

Empiric Selection Criteria

Date :6/19/2005 8:38:17 AM Poster : Marcel

Hi,

I've been developing and practicing very intensively with NST Pro for the last 3-4 months, working 15h a day including weekends; I've built a few dozens of models, screened and tested almost a thousand of stocks with them, and finally selected 30 that I'm now actively trading with a handful of models.

Besides a few lucky trades, I'm however not yet satisfied with my results – the winners/losers ratio of the traded stocks is 30-40%, while I was expecting it to be at least above 50%.

At this point in time there is one important question that bothers me – What are the criteria that qualifies a stock/model for trading?

Analyzing charts, plotting meaningful indicators, building models based on NNs, testing, backtesting etc. are all necessary steps, results of which are in the end proven with good/positive Out of Sample statistics. For example, I set my criteria to >70% successful trades, double performance than buy & hold but at least 30% on a yearly basis, and last but not least a visually attractive chart with the buy/sell signals placed at the right turning points and no major mistrades or periods of inactivity in the Out of Sample chart.

I'm aware about the risks of overfitting, therefore I make only little usage of optimization, limit the amount of EoD data to 4-5 years and usually define a few walk-forward test periods of 6 months.

Now back to my original question:

- On the basis of which empirical criteria do you qualify for trading a stock/model that performs well during the Out of Sample period?

- What gives you the certitude that the stock/model will in reality perform nearly as good as during the Out of Sample period, at least for a few months, after which retraining will probably be required?

- What do you do to ascertain and limit the risk that a stock/model does not "go crazy" once trading has begun and totally misbehave?

- Is there any documentation on this subject?

I appreciate all objective and founded comments on the above.

Thanks in advance,
Marcel

Marcel:

I love hearing about people putting in extraordinary hours in pursuit of their goals. I've recently returned to NST Pro after an extended break because my own intuitive trading has turned . . . ahem . . . unprofitable.

Never having visited before, I came to this forum a couple of days ago and began reading the threads chronilogically from Steve Ward's welcome comment in 2000. Skipping only the thread titles regarding data vendor issues, I've read about a year's worth (extemely slow . . . reader). I can't recommend this enough! It takes a while, but the folks at WSG and NST users have done a tremendous amount of work addressing these and many more issues. I remember reading frequent references to this forum in the documentation, but never resolved to simply start reading it (rather than searching it for a specific answer).

I am less experienced with the product than you are, and I may have misunderstood your questions, but I am confident you would be well served by undertaking to just start reading this forum from the beginning. Again, if you have already done that, I apologize. You will come across posts from users that may not have the exact same question as yours, but who approach trading in a very similar way, and their discussions will be especially useful in expanding your perspective. On more than one occasion, a user noted that if the forum had been created a year earlier, they would have saved months and months of working in unproductive directions. The same must be true of us (not you, necessarily, but me . . . and whoever else neglects this amazing resource).

As to your specific questions, sorry to blow you off like this, but I really feel qualified only to relay my good fortune at having come across your answers below. I'm going to follow up this post by reviewing what I've read of the forum so I can make specific thread suggestions. I would attempt to answer you more directly, but I'm so new, I feel like the proverbial mortal before giants here.

Josh,

Many thanks for your valuable input. Don't underestimate yourself, every answer, tip or comment can help myself or others. Sometimes it's exactly those simple things that provide the correct direction, which ultimately leads to resolutions.

Wrt previous discussion threads, yes, I've read a few, but I definitely didn't have the patience to go through as many as you did. I've also found the dicussion forum software to be a bit user unfriendly when you want to dig into past threads, but this can't be used as a pretext.

I may have to take the time and dig into them, so far however I haven't found the answers I'm looking for.

User unfriendly forum format

Date :6/23/2005 9:03:19 AM Poster : josh

"User unfriendly." Well said. I would appreciate it if a "thread" linked to a dynamically amended page that contained the post and the replies in their totality. I actually read a thread started by the good folks at WSG in which they discussed their difficulties in making the forum all things to all people, but that was back in 2000-01. Might they reconsider adopting a more widely accepted "blog" format? I'm continually impressed with their level of customer service and their supervision of the forum, so I hesitate to ask them to make any trade-offs to spend the time overhauling. This might be a good job to outsource to someone who would take NST in trade for blog hosting or something.

We agree. We were actually thinking of starting a second forum in that format with the introduction of release 5.0, because it would be very time consuming to try to convert the existing posts. Our AI College forum has always been in that format, and it worked pretty well.

Marcel:

Here are the threads that came to mind upon reading your questions. Seems like none ask your exact questions, but deal with similar issues. Listed according to how I perceive their relevance to you:

"Before entering the market," posted by Jacobs, 11/28/2000
"General Advice . . .," posted by Ian, 9/7/2000
"What issue to pick," posted by Steve Ward, 10/26/2000
"Evaluate a model- me?," [lol] posted by Jacobs, late 2000 (forgot to jot date)

And others! Hope this has been some help. Don't forget to take a break to eat and look outside. Good luck!

Josh

Hi,

I've been developing and practicing very intensively with NST Pro for the last 3-4 months, working 15h a day including weekends; I've built a few dozens of models, screened and tested almost a thousand of stocks with them, and finally selected 30 that I'm now actively trading with a handful of models.

Besides a few lucky trades, I'm however not yet satisfied with my results – the winners/losers ratio of the traded stocks is 30-40%, while I was expecting it to be at least above 50%.

At this point in time there is one important question that bothers me – What are the criteria that qualifies a stock/model for trading?

Analyzing charts, plotting meaningful indicators, building models based on NNs, testing, backtesting etc. are all necessary steps, results of which are in the end proven with good/positive Out of Sample statistics. For example, I set my criteria to >70% successful trades, double performance than buy & hold but at least 30% on a yearly basis, and last but not least a visually attractive chart with the buy/sell signals placed at the right turning points and no major mistrades or periods of inactivity in the Out of Sample chart.

I'm aware about the risks of overfitting, therefore I make only little usage of optimization, limit the amount of EoD data to 4-5 years and usually define a few walk-forward test periods of 6 months.

Now back to my original question:

- On the basis of which empirical criteria do you qualify for trading a stock/model that performs well during the Out of Sample period?

- What gives you the certitude that the stock/model will in reality perform nearly as good as during the Out of Sample period, at least for a few months, after which retraining will probably be required?

- What do you do to ascertain and limit the risk that a stock/model does not "go crazy" once trading has begun and totally misbehave?

- Is there any documentation on this subject?

I appreciate all objective and founded comments on the above.

Thanks in advance,
Marcel

Re: Empiric Selection Criteria

Date :6/22/2005 12:02:46 PM Poster : Marcel

Maxwell,

All the models I'm using for trading are conceptually similar, i.e. enhanced versions of one of the examples provided on the CD (I think it's Example 6). I have 3 NNs that independently deliver signals to a trading strategy, which ultimately decides whether to go short/long.

No model has the same set of NNs. In one model the 3 NNs take input from different categories of indicators, while in another the 3 NNs use the same indicators, but set in such way that they consider different timings (short/medium/long term).

To answer your questions, the inputs per NN vary from 3 to 6.

Marcel

That doesn't sound like too many inputs. What time frame are you using for training? Does the market exhibit strong moves in both directions during this time frame? What objective function are you using?

Maxwell,

As stated in my original message, the training is limited to 4-5 years and I usually define 2 walk-forward test periods of 6 months.

Yes, it can happen that the price charts exhibit break-outs in both directions. I know that there is a practice of selecting only stocks that have recurring trend patterns. But instead of subjectively filter those out, I let the statistics tell me: Strong moves during the training phase will sensibly condition the nets, and if those moves are not present anymore in the out of sample period, it will result in very few signals and usually bad relative performance.

With regards to Objective Function, I've had the best results with "Maximize Return on Account". I do however sometimes also use "Maximize #Winners - #Losers".

Marcel

I would like to describe my thought process on the subject. Maybe you are way ahead of this, but here goes:

First rule of trading/risk management/money management = Love Your Losers. Accept that there will be losers and develop a system that requires you to take them in proportion to total equity. The book "Market Wizards," my favorite industry book of all time, demonstrates over and over again that the discipline to take your losses is tops. Most of the traders interviewed set their max loss-per-trade to total equity ratio at between 2 - 5%. If you have $100,000 equity, you risk no more than $2,000 -$5,000 on any trade. So I have been stabbing at a model that not only gets it right, but that limits the max drawdown. So I've had most luck with Limit Max Drawdown when plugging inputs into Prediction Wizard.

Of course, when taking an indicator that has been vetted and optimized with the Prediction Wizard and used to build a Trading Strategy, I would never have thought you could have any confidence that your Strategy, using only the inputs given, would come up with entry and exit signals GUARANTEEING similar risk management characteristics to the Predicted inputs. It is my belief that you have the option of putting an exit condition or a "reverse" condition, but you must enter a "stop" in order to guarantee loss limits. So far (and I am painfully new to this) entering these things has completely screwed the predicted pooch when I try to generate a decent Trading Strategy.

I wonder if its possible to pass on these loss limit rules to the prediction wizard when you're looking for inputs in the first place? In other words, look for parameters that can allow max drawdown to float, and that understands that there must be a loss limit.

This is a long post, so I'll post again when discussion runs to ratios of "evaluation bars" to "Out of sample bars." I have a theory for determining these I'd like to set up for debunking!

Josh

I don't think its possible to add stops and such like into the Prediction Wizard. The way I do it is to use one of the Neural Add-ons and use that in a trading strategy when on can use the stops.

Maciej:

'I don't think its possible to add stops and such like into the Prediction Wizard.'

Thanks for the reply. I meant to suggest that it would be nice if the Prediction Wizard could handle the concept of stops in a future release of NST. I feel like I'm missing a fundamental concept behind NST.

'The way I do it is to use one of the Neural Add-ons and use that in a trading strategy when on can use the stops.'

I have toyed briefly with Neural Add-ons myself in the Trading Wizard (following the examples with recur and jump indicators), but I can't say as I truly understand what is happening. Would you mind giving me a rough idea how you put together a Trading Strategy with the inputs you like from the Prediction Wizard using Neural Add-ons, and being specific in how you specify exit and stop signals?

-Josh

Hi,

I've been developing and practicing very intensively with NST Pro for the last 3-4 months, working 15h a day including weekends; I've built a few dozens of models, screened and tested almost a thousand of stocks with them, and finally selected 30 that I'm now actively trading with a handful of models.

Besides a few lucky trades, I'm however not yet satisfied with my results – the winners/losers ratio of the traded stocks is 30-40%, while I was expecting it to be at least above 50%.

At this point in time there is one important question that bothers me – What are the criteria that qualifies a stock/model for trading?

Analyzing charts, plotting meaningful indicators, building models based on NNs, testing, backtesting etc. are all necessary steps, results of which are in the end proven with good/positive Out of Sample statistics. For example, I set my criteria to >70% successful trades, double performance than buy & hold but at least 30% on a yearly basis, and last but not least a visually attractive chart with the buy/sell signals placed at the right turning points and no major mistrades or periods of inactivity in the Out of Sample chart.

I'm aware about the risks of overfitting, therefore I make only little usage of optimization, limit the amount of EoD data to 4-5 years and usually define a few walk-forward test periods of 6 months.

Now back to my original question:

- On the basis of which empirical criteria do you qualify for trading a stock/model that performs well during the Out of Sample period?

- What gives you the certitude that the stock/model will in reality perform nearly as good as during the Out of Sample period, at least for a few months, after which retraining will probably be required?

- What do you do to ascertain and limit the risk that a stock/model does not "go crazy" once trading has begun and totally misbehave?

- Is there any documentation on this subject?

I appreciate all objective and founded comments on the above.

Thanks in advance,
Marcel

I use the add-ons too because they offer a lot of advantages. However, you can also stick a net made with the Prediction Wizard into a trading strategy, then add stops there.

On 6/27/2005 5:23:11 PM Maciej wrote:
I don't think its possible to add stops and such like into the Prediction Wizard. The way I do it is to use one of the Neural Add-ons and use that in a trading strategy when on can use the stops.

I would like to describe my thought process on the subject. Maybe you are way ahead of this, but here goes:

First rule of trading/risk management/money management = Love Your Losers. Accept that there will be losers and develop a system that requires you to take them in proportion to total equity. The book "Market Wizards," my favorite industry book of all time, demonstrates over and over again that the discipline to take your losses is tops. Most of the traders interviewed set their max loss-per-trade to total equity ratio at between 2 - 5%. If you have $100,000 equity, you risk no more than $2,000 -$5,000 on any trade. So I have been stabbing at a model that not only gets it right, but that limits the max drawdown. So I've had most luck with Limit Max Drawdown when plugging inputs into Prediction Wizard.

Of course, when taking an indicator that has been vetted and optimized with the Prediction Wizard and used to build a Trading Strategy, I would never have thought you could have any confidence that your Strategy, using only the inputs given, would come up with entry and exit signals GUARANTEEING similar risk management characteristics to the Predicted inputs. It is my belief that you have the option of putting an exit condition or a "reverse" condition, but you must enter a "stop" in order to guarantee loss limits. So far (and I am painfully new to this) entering these things has completely screwed the predicted pooch when I try to generate a decent Trading Strategy.

I wonder if its possible to pass on these loss limit rules to the prediction wizard when you're looking for inputs in the first place? In other words, look for parameters that can allow max drawdown to float, and that understands that there must be a loss limit.

This is a long post, so I'll post again when discussion runs to ratios of "evaluation bars" to "Out of sample bars." I have a theory for determining these I'd like to set up for debunking!

Yes, it can happen that the price charts exhibit break-outs in both directions. I know that there is a practice of selecting only stocks that have recurring trend patterns. But instead of subjectively filter those out, I let the statistics tell me: Strong moves during the training phase will sensibly condition the nets, and if those moves are not present anymore in the out of sample period, it will result in very few signals and usually bad relative performance.

With regards to Objective Function, I've had the best results with "Maximize Return on Account". I do however sometimes also use "Maximize #Winners - #Losers".

Josh, Thanks for your contribution.

I've nothing to add on "Love Your Losers", that's key and goes along with the principle of "Strictly following and applying discipline". I do also underwrite to the Risk Mgmt comments, although in this context I'd rather call it Money Mgmt. No strategy is efficient without a proper Money Mgmt umbrella.

For this reason I've adopted the practice to set stop loss limits quite a while ago. My experience is that incorporating stop losses while building and training models and strategies is not effective, as you say it screwes up the outcome. Depending on the model, sometimes you simply end up in having a number of little consequent losers instead of a bigger single draw down. Stop losses are however very efficient in the Money Mgmt context, as an overall strategy outside of NST, that's where in my opinion it has to be applied.

Marcel

I have two suggestions. First, try using another objective function. The one I like is return on account*equity curve correlation, having become accustomed to it from something that I read here or in a discussion with someone at Ward Systems, I forget which. What you are looking for is a smoothly rising equity curve, not too steep, but gentle in nature, which might answer your original question.

Second I read in one of your posts that you are using Jurik indicators, though I don't think you mentioned which ones. Be very careful with any type of moving averages, whether they are so called adaptive or not. Moving averages are like price, and thus not detrended. It is better to use spreads or percent spreads between moving averages, or other detrenders applied to them. If you are using moving averages by themselves in a neural network, future price levels essentially match up with smaller portions of the training set.

Good luck.

Thanks Maxwell, I will try your suggetion re objective function in the new set of models due for next month. With regards to Jurik indicators, I avoid the direct usage of moving averages for the reasons you explained below. I make instead use of combinations of CFB, Polarized Fractal Efficiency, Speedy MACD, DMX and RSX - some of them with adaptive source.

Marcel

Re: "- On the basis of which empirical criteria do you qualify for trading a stock/model that performs well during the Out of Sample period?"

My acceptance criteria for a system tested with realistic commissions and slippage:

1. The out-of-sample equity curve moves from the lower left to the upper right hand corner of the chart without significant drawdowns.

2. Max Drawdown of less than 10-15% of the prior peak equity

3. Reasonable values for % Winning Trades and Profit Factors (these are interdependent, so hard fixed numbers can't be given)

4. No significant clusters of alternating buy/sell's on consecutive bars (a major problem with NST if long/short signals are optimized independently, i.e., without all parameters linked).

Re: "- What gives you the certitude that the stock/model will in reality perform nearly as good as during the Out of Sample period, at least for a few months, after which retraining will probably be required?"

The purpose of the out-of-sample test is to give one confidence that the system may continure to perform well on unseen data. But there can be no guarantee that the system will continue to perform well. One can gain additional confidence by testing the system on other instruments/stocks to see how good the generalization is; but there again there is no guarantee on future performance.

Re: "- What do you do to ascertain and limit the risk that a stock/model does not "go crazy" once trading has begun and totally misbehave?"

1. Bet Sizing (money management).

2. Pre-established system termination criteria (e.g., equity curve going south over a given time period or max drawdown greater than X percent, etc.)

Greg,

Thanks very much for your substantial and valuable input - let's hope for some more to come.

I can very well follow your acceptance criteria, interesting for me is your focus on drawdown (prior to performance), which contributes also to risk management.

What raises some additional questions is the middle section: I agree that the Out of Sample period is there to ascertain the validity of the model.

- But what if you select out of a sample of 100 stocks, only the few ones that perform the best?

- Isn't this a kind of "manual fitting"?

- Or have you been able to create models that fulfill acceptance criteria for a large number of stocks?

Thanks also for the literature reference.
Marcel

Hi,

I've been developing and practicing very intensively with NST Pro for the last 3-4 months, working 15h a day including weekends; I've built a few dozens of models, screened and tested almost a thousand of stocks with them, and finally selected 30 that I'm now actively trading with a handful of models.

Besides a few lucky trades, I'm however not yet satisfied with my results – the winners/losers ratio of the traded stocks is 30-40%, while I was expecting it to be at least above 50%.

At this point in time there is one important question that bothers me – What are the criteria that qualifies a stock/model for trading?

Analyzing charts, plotting meaningful indicators, building models based on NNs, testing, backtesting etc. are all necessary steps, results of which are in the end proven with good/positive Out of Sample statistics. For example, I set my criteria to >70% successful trades, double performance than buy & hold but at least 30% on a yearly basis, and last but not least a visually attractive chart with the buy/sell signals placed at the right turning points and no major mistrades or periods of inactivity in the Out of Sample chart.

I'm aware about the risks of overfitting, therefore I make only little usage of optimization, limit the amount of EoD data to 4-5 years and usually define a few walk-forward test periods of 6 months.

Now back to my original question:

- On the basis of which empirical criteria do you qualify for trading a stock/model that performs well during the Out of Sample period?

- What gives you the certitude that the stock/model will in reality perform nearly as good as during the Out of Sample period, at least for a few months, after which retraining will probably be required?

- What do you do to ascertain and limit the risk that a stock/model does not "go crazy" once trading has begun and totally misbehave?

- Is there any documentation on this subject?

I appreciate all objective and founded comments on the above.

Thanks in advance,
Marcel

Re: Empiric Selection Criteria

Date :6/28/2005 10:56:19 AM Poster : Greg Kramer

Re: "interesting for me is your focus on drawdown (prior to performance)"

Actually, prior to looking at drawdown, the system must first have "good performance" which for me is equity moving from the lower left to upper right. This means that the system is capable of making money and has a positive expectancy.

Re: "But what if you select out of a sample of 100 stocks, only the few ones that perform the best?"

My purpose for out-of-sample testing of additional stocks is test the system with additional data that it has not seen before and to determine if it has generalized its rules or is curved fitted. If only a few of the 100 stocks perform well in an out-of-sample test, then the system has failed to generalize. In this case you may want to attempt to identify why (e.g., the stocks that do well are highly correlated with the stock(s) that you initially trained the system on, etc.).

Re: "Isn't this a kind of "manual fitting"?"

Maybe. But remember that

(1) The system performed well during training;

(2) the system performed well on the initial out-of-sample test on the training instruments/stocks;

(3) the purpose of additional out-of-sample testing on other instruments/stocks was to gain additional confidence and to determine how generalized (vs. curved fitted) the system is.

I see no problem with trading the system on the original instruments/stocks. Of course one could paper trade the system in realtime for some period to gain additional confidence. But at some point you are going to have to belly up to the bar and place your bet with hard cold cash.

Re: "Or have you been able to create models that fulfill acceptance criteria for a large number of stocks?"

Yes.

On 6/27/2005 10:44:44 AM Marcel wrote:
Greg,

Thanks very much for your substantial and valuable input - let's hope for some more to come.

I can very well follow your acceptance criteria, interesting for me is your focus on drawdown (prior to performance), which contributes also to risk management.

What raises some additional questions is the middle section: I agree that the Out of Sample period is there to ascertain the validity of the model.

- But what if you select out of a sample of 100 stocks, only the few ones that perform the best?

Re: "- On the basis of which empirical criteria do you qualify for trading a stock/model that performs well during the Out of Sample period?"

My acceptance criteria for a system tested with realistic commissions and slippage:

1. The out-of-sample equity curve moves from the lower left to the upper right hand corner of the chart without significant drawdowns.

2. Max Drawdown of less than 10-15% of the prior peak equity

3. Reasonable values for % Winning Trades and Profit Factors (these are interdependent, so hard fixed numbers can't be given)

4. No significant clusters of alternating buy/sell's on consecutive bars (a major problem with NST if long/short signals are optimized independently, i.e., without all parameters linked).

Re: "- What gives you the certitude that the stock/model will in reality perform nearly as good as during the Out of Sample period, at least for a few months, after which retraining will probably be required?"

The purpose of the out-of-sample test is to give one confidence that the system may continure to perform well on unseen data. But there can be no guarantee that the system will continue to perform well. One can gain additional confidence by testing the system on other instruments/stocks to see how good the generalization is; but there again there is no guarantee on future performance.

Re: "- What do you do to ascertain and limit the risk that a stock/model does not "go crazy" once trading has begun and totally misbehave?"

1. Bet Sizing (money management).

2. Pre-established system termination criteria (e.g., equity curve going south over a given time period or max drawdown greater than X percent, etc.)

Greg,

Your reply makes me more and more curious...

Re: "the system must first have "good performance" which for me is equity moving from the lower left to upper right"

My understanding is that performance is measured either in $ or %. I actually don't care if the equity has an upward or downward trend, since I trade both long and short. As long as the equity HAS a trend, and as long as this trend is successfully captured/learned by the model and eventually applied in the out-of-sample, for me what counts is the performance in $/% and the ratio of mis-trades. Do I miss anything here? Maybe you are referring to e.g. a NetProfit or SystemEquity curve...

Re: "If only a few of the 100 stocks perform well in an out-of-sample test, then the system has failed to generalize"

I must admit that following the above, ALL my models are failing. If I take for example the Nasdaq 100 set of equities, I usually get only a few "good looking stocks", at best they are in the higher single digit. Considering a training span of 4-5 years, one also has to take into account that the number of stocks that have been following a "normal trend" during this time is very, very scarce. Most of the instruments have been going through the 2000 bubble, a big peak then the decline. Those which didn't were maybe commodity or energy related, and these have gone crazy lately peaking for the last 2 years.

Re: "Or have you been able to create models that fulfill acceptance criteria for a large number of stocks? --> Yes."

This really makes me curious! I'm a bit ashamed to ask this question, but would be willing to share your experience? Ideally, would you be willing to post a few examples (*.cht files) based on current data? I've started another thread "Model Sharing", maybe you want to contribute there...

Thanks a lot!
Marcel

Quote.com problems

Date :6/22/2005 2:03:47 PM Poster : Ward.net Webmaster

Customers have reporting Quote.com problems for days. We have seen many periods when real time data stops. Here is what Quote.com's web site says:

Date: 6/21/2005
Dear QCharts Client:

As you are aware, due to a provider error, we are experiencing incorrect data on the following emini symbols:

NQ - Nasdaq
ES - S&P

MR - Russell

Please be advised that our engineers are have identified a fix that will correct this issue. The fix will be rolled out incrementally after hours throughout this week and will complete this coming weekend. We apologize for any inconvenience this may have caused, and we appreciate your patience.

Sincerely,
The Quote Product Team

In my recent post, I extolled the virtues of pouring over this entire forum as a good idea. I still believe that, and I'm about six months further along. But, I'm not blind to the virtues of a good site search either. Since I haven't found my answer from either of the methods so far, thought I would ask:

What is the best way to compare the US 10yr Note futures (trade from 20:00 to 17:00 EST) to the German 10yr future, the Bund (trade from 02:00 to 13:00 EST).

My observation as a futures trader of 7 years has been that overnight, the Bund moves the US futures, and when the pit opens in Chicago (or up to an hour before) US futures are king. I have no problem cropping the US time series to equal the period of overlap with the German, but what is the best way?

Has anyone else thought to capitalize on the discrepencies between these highly correlated contracts? Success or frustration? I'm only too happy to share my thoughts on promising inputs to optimize (for what their worth) but I can't get my arms around the different session times.

I think I read a discussion of this concept somewhere, but I can't find it with the search. Thanks for any thoughts.

Josh

ESignal - European Futures Continuous contracts

Date :6/25/2005 2:27:51 PM Poster : alex amos

I have always had a problem creating continuous contracts within the Trader. I was therefore very happy when ESignal added this capability with the release of 7.9. My happiness was shortlived when I discovered that the data was only available within Advanced Charting itself. I therefore wrote to ESignal to query why they had not programmed the Data Manager instead of 7.9 . The answer which I eventually received is given below and may be of interest to other disappointed customers of DBC. (As most will know, Greenland will probably melt before the non-American Exchanges incorporate continuous futures data into their feeds.)

"In reply to your question, there are no plans to do this in the datafeed or to try and set up the tool in the data manager. The reason we don't do it in the feed is that we've never been able to get any accurate set of defaults to get this done. There is no standard for when to roll a contract and many of the international contracts are quite complicated on how to do things. Even with the domestic (US) contracts, we've always had negative feedback from users saying that we're not always rolling when they think we should. This would be easier if the exchanges would ever come up with a spec for switching contracts, but I don't see that coming. The reason we don't do this at the data manager level is that it would require too many components be changed and would mean changing the strategy of the data manager. The Data Manager is simply an application that gathers the data and passes it through to the end application requesting the data. Adding logic to do lookups and convert symbols would detract from its current operation. With the current solution within eSignal using continuous contracts, a decision is being made on what the correct symbol is for the current contract and then the request to the data manager is for the actual symbol.

Given this, we decided the best way to finally offer this was the by giving the users the ability to string the contracts together based on their own preferences. We're currently only doing this based on dates, but plan to enhance this over time to include rolls based on Volume and/or Open Interest. None of this can be done on the server end as users have different opinions of what rules to use.

I hope this helps explain some of the reasons for how things work re continuous futures contracts.

Best regards

Grant Dickie

Comment from AA. If the decisions to be made are so subjective, I am at a loss to understand how CME etc cope so admirably and without complaint.

Re: ESignal - European Futures Continuous contracts

Date :10/13/2005 2:33:05 PM Poster : Maciej

You may want to look at CSI for daily continous contracts. NSDT does not autmatically read the data but I've found it probably the most comprehensive for futures. NSDT will read the data.

We aren't sure what you mean by "automatically read" daily data, but if you download CSI data into a folder in either CSI or Metastock format, NSDT will read it each time NSDT is brought up without any action on your part.

Re: ESignal - European Futures Continuous contracts

Date :10/18/2005 11:11:33 AM Poster : Maciej

Perhaps I wasn't clear enough. There is no problem in NSDT reading CSI. What does not exist is the ability to load the latest data from within NSDT as in the case of Quote, Esignal or Prophet to name the ones that I have tried from within NSDT. The level of sophistication with CSI continous contracts is in my limited experience quite large - well beyond the capabilities of the other purveyors of data. The data includes Open Interest as well as Volume O/H/L/C and although I haven't yet tried it, the ability to have several continous contracts ie the current contract as part of a continous contract and also the next contract also as a continous contract. For futures, these are interesting tools (another measure of what's happening is the spread between current and forward futures contracts). There is also in the current beta version the ability to get option data for futures to help judge who's buying / selling futures (Fairly often rather than place a stop I will buy/sell a call or put to use as a stop)

Model Sharing

Date :6/27/2005 11:57:13 AM Poster : Marcel

I know that with this message I'm going to touch "sensitive ground", nevertheless I'm serious about it and wish to explore further.

I ask myself if there would be interest to share Models among members of this forum.

IMHO there are little reasons why not:
- Most of us are using NST for personal rather than corporate interest
- There is only limited IP to be "given away"
- Experience is the essence here, not the results in form of models
- It would be an additional advanced educational enrichment for all of us
- It would help us to relatively compare the quality of our own models
- And generate new idea and ground to work on

From my side I'm willing to share the models I'm trading with. Most of them make use of Jurik indicators, but these can easily be replaced by traditional indicators with some performance decrease to be expected. I'm using EoD data only, not sure if models can be used for Intraday too.

Your thoughts and comments are welcome.
Marcel

Re: Model Sharing

Date :6/27/2005 3:24:57 PM Poster : josh

Marcel-

I am interested in sharing. There is a quasi-precedent for this practice dating back to 2000-01 among individuals collaborating on a system. Wonder how they got along? Their posts were entertaining to read as they developed criteria for issue selection, objectives to predict, inputs they like, etc. If I had a profitable model I would share it in this post. Alas, I am not working on that skill set yet. Have you ever seen Karate Kid? I'm still at "wax on! wax off!" I.e. working on getting the Prediction Wizard to optimize my inputs and parameters to result in 5 out of 5 profitable walk forwards. Maybe I should ease up on my input criteria before trying to codify trading rules?

Some of the inputs I'm toying with are BBands, stochastics, old highs and lows, as well as Turning Point, Advanced Indicator Sets, Clusters and Fuzzies. In reality, I think there are more than enough indicators included in the program to keep someone new like myself busy for a year or two. I appreciate your suggestion to exclude add-on indicators in shared models.

You alluded to the school of thought that argues against sharing "the total package." (my term) I don't subscribe to that, but like you, I have the upmost respect for those who do. We all know how much work goes into a successful model (more than I've put in!). I simply don't think enough people could copy a strategy and implement a trading program based on it to significantly influence the S/D of highly liquid stocks before the market changes of its own volition rendering the strategy obsolete anyway. So, for me, sharing is merely akin to fleshing out the excellent examples included in the software- something I hope to do for as long as I'm using this product. For others, it may seem like shoothing themselves in the foot.

Re: Model Sharing

Date :6/27/2005 5:17:47 PM Poster : Maciej

I can understand people's reluctance to share models particularly as most of these systems represent considerable effort which no one wants to give away. The reality is that its most unlikely that any two of us will trade a given system in exactly the same way unless it were totally mechanised including the trigger pulling part. An example in the public domain is the turtle trading system - we all know how it works but few of us have the account size or temperament to trade it.

'I can understand people's reluctance to . . .'

Agreed.

'An example in the public domain is the turtle trading system . . .'

You may be interested in this. I bought the turtle program a few years ago. In it they extolled the virtues of the trend trading philosophy: citing statistics on trending vs. non-trending periods, the phenomenon of trends showing up in coin flips, etc. (I haven't plugged it into trading system software to test it because I've never learned how to account for changing position size.) But anecdotal evidence suggests those using the system suffered a period back then that wiped many out. Perhaps because there were so many users? I don't know the answer to that. The futures markets entered a non-trending period of sustained duration to the extent that Richard Dennis closed up shop. (He may have reopened as the markets have been looking more trendy in the last year or so)

My gut is that the turtles brought attention to the overall phenomenon of trend following because it was such an easy idea to understand, and that successful models developed with much help from NST would hinge on theories less easily articulated and therefore not mass distributed.

I'm sure you didn't mean it this way, but just to clarify, the Turtle system is not in the public domain, although it might as well be, as you said, "we all know how it works."

Finally, wouldn't it be cool to arrive at a new theory, as easy to understand as "trend following," that revolutionized the risk-management industry? Talking about this makes me want to re-read "The New Market Wizards," almost as good as the first one, but seems more focused on systems traders. Reading that series always gets me pumped.

Re: Model Sharing

Date :6/30/2005 9:59:14 AM Poster : Steve Eberbach

Funny thing, this Synchronicity!

I also am reading "The New Market Wizards", and am getting very pumped. Trading is so complex that it is very difficult for a single person to "do it all" themself. It takes a team of people with various talents working together with psychological diversity and checks and balances, unless you are one of those "multi" types with perfectly disciplined ADHD.

I am grateful to have Steve Ward and Co. on my little team.

You no longer have to buy the original Turtles' strategy to learn it.
Have even been modelling the "Turtle system", which you can read about at:

http://www.originalturtles.org/system.htm

The tough part is the putting-on-positions rules requiring a time/price-diversified staged entry and exit strategy, but it is key, mathematically, to the success, which I have verified to my own satisfaction with NST, using overlaid strategies. (See tips) I have only verified some of the principles involved with "Turtle-like" models.

The real thing is really much more difficult to model and execute than the more typical signal-and-threshold paradigm, but a breakout stop-order Template (in trading strategy wizard) which is [almost] always trying to enter the market OPPOSITE the current position with stop orders is my starting point. The simplest stops are Lag(Max,PriceTimeSeries), spanbars3lagbars) and Lag(Min(PriceTimeSeries) spanbars3lagbars. Just like the original Turtles' "Breakouts". Layer on more copies of basic strategy with stops offset in price to simulate staged entries, exits, reversals. You have to begin by assuming you will Timing-diversify using several contracts, or "lots" of stock shares.

Also key to success is being able to diversify among instruments of trading, because nothing trends all the time, let alone trends all the time in just one direction. It is analogous to catching popcorn just as it is popping. Focussing on each popping kernel one at a time is a frustrating exercise at best.

Thanks, Steve.

". . . but a breakout stop-order Template (in trading strategy wizard) . . . is my starting point."

That is a fascinating concept. But- and don't take this the wrong way- by any chance did you arrive at that strategy after repeated attempts to develop a "successful" trading system resulted in developing a wonderfully consistent "losing" trading system? A.k.a. The Un-Holy Grail? The Anti-Grail? I ask because I think I'm closer to cracking that mystery than I am to a decent model. The thought has occurred to me at times that I should be able to safely take the opposite positions of my strategy's signals and do quite well.

If I understand you correctly, your model has the following characteristics:

it relies on "sub-models" for entry conditions
sub-models take the theories of the turtle system (based primarily on the identification of trends) and creates simple entry signals and stops.
the trading model takes the sub-models' stop signals for it's entry signals
you use portfolios of trading models to diversify among issues and time frames

Can't an entry signal using another model's stop signal be instead positively identified with an indicator? Is it easier for one to generate the multiple layer models (for a variety of issues)-- necessary to diversify across time-- by beginning with a first model that generates stop signals? As you diversify across time, is it your hope/expectation that, although you may lose one or two or five in a row, ultimately you will have a bunch of individually deployed signals ganging up on a trend?

"The simplest stops are . . ."

Oy, vay! As I've stated recently, I'm still a newbie here, so maybe when I butted in asking for specifics, I stepped in it. I still have some larger issues I need to arrive at on my own through trial and error screwing around. I really appreciate your willingness to lay it out like that, Steve.

Marcel, thanks for starting this thread! Hope I haven't steered it too far from your original goal.

I am interested in sharing. There is a quasi-precedent for this practice dating back to 2000-01 among individuals collaborating on a system. Wonder how they got along? Their posts were entertaining to read as they developed criteria for issue selection, objectives to predict, inputs they like, etc. If I had a profitable model I would share it in this post. Alas, I am not working on that skill set yet. Have you ever seen Karate Kid? I'm still at "wax on! wax off!" I.e. working on getting the Prediction Wizard to optimize my inputs and parameters to result in 5 out of 5 profitable walk forwards. Maybe I should ease up on my input criteria before trying to codify trading rules?

Some of the inputs I'm toying with are BBands, stochastics, old highs and lows, as well as Turning Point, Advanced Indicator Sets, Clusters and Fuzzies. In reality, I think there are more than enough indicators included in the program to keep someone new like myself busy for a year or two. I appreciate your suggestion to exclude add-on indicators in shared models.

You alluded to the school of thought that argues against sharing "the total package." (my term) I don't subscribe to that, but like you, I have the upmost respect for those who do. We all know how much work goes into a successful model (more than I've put in!). I simply don't think enough people could copy a strategy and implement a trading program based on it to significantly influence the S/D of highly liquid stocks before the market changes of its own volition rendering the strategy obsolete anyway. So, for me, sharing is merely akin to fleshing out the excellent examples included in the software- something I hope to do for as long as I'm using this product. For others, it may seem like shoothing themselves in the foot.

Re: Model Sharing

Date :7/1/2005 6:42:14 PM Poster : Steve Eberbach

Josh:

I do not think you have steered this topic off Marcel's track at all. In fact the track is getting more solid as we build it. We could change its title to

"Sharing Experiences" to include more generality, just as the "New Market Wizards" shared even more important information in the format of

experiences than they did in the form of "models". Marcel himself said experience is the essence from his own viewpoint. I think that is the purpose

behind Steve Ward's creating this fourm as support of the software.

Quoting Monroe Trout from "The New Market Wizards": " ..if we blindly followed the systems we might make half of what we do now. Maybe even less.

I could give 10 CTAs the exact systems we use, and some of them still wouldn't make any money."
Now, a CTA is a pro by definition, running his/her modelling advice as a serious business.

Put that together with the fact that Trout's team of traders trades from MODELS, many of them, just like users of NeuroShell Trader Pro! Make your

own inferences from that! Maybe Trout even uses NST pro and a team of modelling Geeks instructing his Floor traders!

To be repetitive:

Marcel says: "EXPERIENCE is the essence here". More thanks for starting this thread, Marcel!

Really practical, tradable "total packages" will be a complex of "edges", (models which really work) and good money managemant, just as Trout

said. (Unless you don't believe a successful multi-millionaire trader) If you read between the lines in Trout's and others' interviews, we little Traders

have an edge called small size. We can execute our entire position faster!

The edge from any particular trading model will break down if there is too much size being triggered by its signals. (a factoid from the wizards'

combined experience)

To answer Josh's particular questions:

Yes, you understood very well what I was saying, and said it back in your own words even better than I explained it.

Yes, an entry signal using another model's stop can be "identified with an indicator".

An example would be: SUB(position (StopStrategy)), lag1 (position (StopStrategy))

A change in position from hitting the stop generates a indicator spike one bar later. Using an indicator directly to give a signal would work to give a

go or no-go for the next bar, but would not give you exact feedback from stop price for the optimizer through the equity curve, drawdown accumulation,

etc. because of the equity posting delay from only marking price at the close or next bar open to your equity total accumulation.

The example I gave gives a SIGNAL one bar late. The SIGNAL from the basic stop strategy Template is "always try to trade next bar against current

position, and do so when stop is hit". So you cannot use the signals (there is a signal every bar), you have to use the actual position of the stop

strategy as the input for your strategy which combines the simpler models. While your stop-based strategies change position inside the bars, the

signals are "known" only at the close. I call such models by the name "Discovery At Close" (DAC) models to remind me of that.

How does this relate to Anti Grail? While it is not motivated by it, it is as you suspect, related. See Steve Ward's post in the tips about "Bizarro".

Example: We know (from reading Market Wizards!) that the Big-Firm floor traders can move prices to hit the stops we just set up in our Turtle-like

template. While they succeed, the equity curve of our stop model suffers a declining trend. But they don't always succeed, or they would be long ago

retired. (Unless they are obsessed, in which case their "size" gets too obvious and cumbersome) So what I try to do with the NST optimizer, is find

what conditions under which their strategy of "running the stops" fails or succeeds. When my equity curve falls, the floor traders are winning, when it

rises, something bigger is overwhelming their little game. That is an example of what I would call a "Strategy". You can try to extract information from

the market prices based on modelling what the traders admit they are looking at when they trade, and rather than blindly following their methods, try

to decide who is winning, and who is losing, and when, and how much. One trend you CAN depend on is that the game goes on and on. The

traders won't stop hitting the ball back and forth.

Referring to the Turtles-style Breakout example, the Strategy Template can mark the STOP PRICE (hypothetically) execution to market equity instead

of the closing price or next bar opening price. The Strategy Wizard puts the red and blue X's right at the stop prices; they are reflected in your trading

statistics you optimize with the optimizer, but you still don't know how many times the actual price crossed the Stop!!!!! Maybe you paid ten times for

just one trade! Really you would need tick data or a trader on the floor. That's probably a decent example of what Trout means when he says his

EXPERIENCE with computer models (in New Market Wizards) is that maybe half his profits are the "edge" from the models, and the other half from

discretionary execution, etc.

Thanks, Steve.

". . . but a breakout stop-order Template (in trading strategy wizard) . . . is my starting point."

That is a fascinating concept. But- and don't take this the wrong way- by any chance did you arrive at that strategy after repeated attempts to develop a "successful" trading system resulted in developing a wonderfully consistent "losing" trading system? A k.a. The Un-Holy Grail? The Anti-Grail? I ask because I think I'm closer to cracking that mystery than I am to a decent model. The thought has occurred to me at times that I should be able to safely take the opposite positions of my strategy's signals and do quite well.

If I understand you correctly, your model has the following characteristics:

it relies on "sub-models" for entry conditions

sub-models take the theories of the turtle system (based primarily on the identification of trends) and creates simple entry signals and stops.
the trading model takes the sub-models' stop signals for it's entry signals
you use portfolios of trading models to diversify among issues and time frames

Can't an entry signal using another model's stop signal be instead positively identified with an indicator? Is it easier for one to generate the multiple layer models (for a variety of issues)-- necessary to diversify across time-- by beginning with a first model that generates stop signals? As you diversify across time, is it your hope/expectation that, although you may lose one or two or five in a row, ultimately you will have a bunch of individually deployed signals ganging up on a trend?

"The simplest stops are . . ."

Oy, vay! As I've stated recently, I'm still a newbie here, so maybe when I butted in asking for specifics, I stepped in it. I still have some larger issues I need to arrive at on my own through trial and error screwing around. I really appreciate your willingness to lay it out like that, Steve.

Marcel, thanks for starting this thread! Hope I haven't steered it too far from your original goal.

Funny thing, this Synchronicity!

I also am reading "The New Market Wizards", and am getting very pumped. Trading is so complex that it is very difficult for a single person to "do it all" themself. It takes a team of people with various talents working together with psychological diversity and checks and balances, unless you are one of those "multi" types with perfectly disciplined ADHD.

I am grateful to have Steve Ward and Co. on my little team.

You no longer have to buy the original Turtles' strategy to learn it.
Have even been modelling the "Turtle system", which you can read about at:

http://www.originalturtles.org/system.htm

The tough part is the putting-on-positions rules requiring a time/price-diversified staged entry and exit strategy, but it is key, mathematically, to the success, which I have verified to my own satisfaction with NST, using overlaid strategies. (See tips) I have only verified some of the principles involved with "Turtle-like" models.

The real thing is really much more difficult to model and execute than the more typical signal-and-threshold paradigm, but a breakout stop-order Template (in trading strategy wizard) which is [almost] always trying to enter the market OPPOSITE the current position with stop orders is my starting point. The simplest stops are Lag(Max,PriceTimeSeries), spanbars)lagbars) and Lag(Min(PriceTimeSeries) spanbars)lagbars. Just like the original Turtles' "Breakouts". Layer on more copies of basic strategy with stops offset in price to simulate staged entries, exits, reversals. You have to begin by assuming you will Timing-diversify using several contracts, or "lots" of stock shares.

Also key to success is being able to diversify among instruments of trading, because nothing trends all the time, let alone trends all the time in just one direction. It is analogous to catching popcorn just as it is popping. Focussing on each popping kernel one at a time is a frustrating exercise at best.

'I can understand people's reluctance to . . .'

Agreed.

'An example in the public domain is the turtle trading system . . .'

You may be interested in this. I bought the turtle program a few years ago. In it they extolled the virtues of the trend trading philosophy: citing statistics on trending vs. non-trending periods, the phenomenon of trends showing up in coin flips, etc. (I haven't plugged it into trading system software to test it because I've never learned how to account for changing position size.) But anecdotal evidence suggests those using the system suffered a period back then that wiped many out. Perhaps because there were so many users? I don't know the answer to that. The futures markets entered a non-trending period of sustained duration to the extent that Richard Dennis closed up shop. (He may have reopened as the markets have been looking more trendy in the last year or so)

My gut is that the turtles brought attention to the overall phenomenon of trend following because it was such an easy idea to understand, and that successful models developed with much help from NST would hinge on theories less easily articulated and therefore not mass distributed.

I'm sure you didn't mean it this way, but just to clarify, the Turtle system is not in the public domain, although it might as well be, as you said, "we all know how it works."

Finally, wouldn't it be cool to arrive at a new theory, as easy to understand as "trend following," that revolutionized the risk-management industry? Talking about this makes me want to re-read "The New Market Wizards," almost as good as the first one, but seems more focused on systems traders. Reading that series always gets me pumped.

Re: Model Sharing
Date :7/7/2005 2:55:24 PM Poster : Marcel

All,

First of all, thanks for keeping this thread alive while I was away - following Josh's advice (http://www.ward.net/cgi-bin/Forum/Forum_Article.asp?a=2465), I've taken a break to recharge my batteries...

It's very interesting to read all your comments and to assure Josh and Steve, I've absolutely no issues with how this thread is evolving. I fully concur with Steve that the main aim is to SHARE EXPERIENCES, to learn, to avoid costly mistakes, to become better and ultimately be able to exercise some profitable trades.

But I'm also a very pragmatic and practical guy, and I feel like taking the (maybe arrogant) liberty to make a plea:

"Dear experienced users of NST, please share your models, the more the better. You will have the opportunity to see and analyze models of your peers and fine-tune your own ones."

To be straight-forward and direct, I believe we should start to share some successful *.cht files based on UP-TO-DATE DATA. Most of the NST users have in their earlier days probably gone through many of the available examples or templates on CD or posted on the Ward Systems site, only to find out that these were successful for PRECISELY the dates they were posted. If you move forward or backward the (model) dates, their performance drastically drops until becoming negative. If you apply them to other stocks, it simply doesn't work.

So I ask myself:
- How do contemporary models look alike?
- Do they still exist, considering that stocks falling out of "normal trends"
are becoming the norm (2000 bubble, commodity/energy rush)?
- Are my models good enough -- or unacceptable for others?

Thanks!
Marcel

Re: Model Sharing

Date :7/11/2005 2:51:17 PM Poster : Mark Simpson

Hi All,

To me, a model is the end result of a process, and that the best
place to start is finding out what needs to be done, then finding/building the tools
to achieve that and then finally ending up with a working model, rather than just
trying to find a working model.

Another way of looking at it is, are we looking to be provided a rod, line and the location, or do we want to learn how to fish?

Models tend to be very specific to peoples risk level, trading timeframes and interests.
An ideal model for one individual probably isn't ideal for another. Also people
tend to have a lot of IP tied up in their models, so are generally unwilling to share
due to the risks involved in doing so. However, people quite often are willing to share
concepts, methods or techniques.

Howabout a discussion starting with "What needs to be achieved to build a profitable
Neural Net"?

Then maybe we could progress into a discussion about the tools/needed. Suggested
items to start with could be:

1. What neural networks can learn, and what they can't learn.
2. Heisenberg, Filters, What is lag. Removing lag, and creating/using
leading indicators.
2. Curve fitting. What it is, how to avoid it and how to use it to advantage.
3. Normalizing Time.

I also, don't want to misdirect this thread. If there's enough interest, then I'll
start the discussion with a "demonstration model" that can be used to figure out
the first question "What needs to be achieved to build a profitable
Neural Net?".

All,

First of all, thanks for keeping this thread alive while I was away - following Josh's advice (http://www.ward.net/cgi-bin/Forum/Forum_Article.asp?a=2465), I've taken a break to recharge my batteries...

It's very interesting to read all your comments and to assure Josh and Steve, I've absolutely no issues with how this thread is evolving. I fully concur with Steve that the main aim is to SHARE EXPERIENCES, to learn, to avoid costly mistakes, to become better and ultimately be able to exercise some profitable trades.

But I'm also a very pragmatic and practical guy, and I feel like taking the (maybe arrogant) liberty to make a plea:

"Dear experienced users of NST, please share your models, the more the better. You will have the opportunity to see and analyze models of your peers and fine-tune your own ones."

To be straight-forward and direct, I believe we should start to share some successful *.cht files based on UP-TO-DATE DATA. Most of the NST users have in their earlier days probably gone through many of the available examples or templates on CD or posted on the Ward Systems site, only to find out that these were successful for PRECISELY the dates they were posted. If you move forward or backward the (model) dates, their performance drastically drops until becoming negative. If you apply them to other stocks, it simply doesn't work.

So I ask myself:
- How do contemporary models look alike?
- Do they still exist, considering that stocks falling out of "normal trends"
are becoming the norm (2000 bubble, commodity/energy rush)?
- Are my models good enough – or unacceptable for others?

Thanks!
Marcel

Josh:

I do not think you have steered this topic off Marcel's track at all. In fact the track is getting more solid as we build it. We could change its title to

"Sharing Experiences" to include more generality, just as the "New Market Wizards" shared even more important information in the format of

experiences than they did in the form of "models". Marcel himself said experience is the essence from his own viewpoint. I think that is the purpose

behind Steve Ward's creating this fourm as support of the software.

Quoting Monroe Trout from "The New Market Wizards": " ..if we blindly followed the systems we might make half of what we do now. Maybe even less.

I could give 10 CTAs the exact systems we use, and some of them still wouldn't make any money."
Now, a CTA is a pro by definition, running his/her modelling advice as a serious business.

Put that together with the fact that Trout's team of traders trades from MODELS, many of them, just like users of NeuroShell Trader Pro! Make your

own inferences from that! Maybe Trout even uses NST pro and a team of modelling Geeks instructing his Floor traders!

To be repetitive:

Marcel says: "EXPERIENCE is the essence here". More thanks for starting this thread, Marcel!

Really practical, tradable "total packages" will be a complex of "edges", (models which really work) and good money managemant, just as Trout

said. (Unless you don't believe a successful multi-millionaire trader) If you read between the lines in Trout's and others' interviews, we little Traders

have an edge called small size. We can execute our entire position faster!

The edge from any particular trading model will break down if there is too much size being triggered by its signals. (a factoid from the wizards'

combined experience)

To answer Josh's particular questions:

Yes, you understood very well what I was saying, and said it back in your own words even better than I explained it.

Yes, an entry signal using another model's stop can be "identified with an indicator".

An example would be: SUB(position (StopStrategy)), lag1 (position (StopStrategy))

A change in position from hitting the stop generates a indicator spike one bar later. Using an indicator directly to give a signal would work to give a

go or no-go for the next bar, but would not give you exact feedback from stop price for the optimizer through the equity curve, drawdown accumulation,

etc. because of the equity posting delay from only marking price at the close or next bar open to your equity total accumulation.

The example I gave gives a SIGNAL one bar late. The SIGNAL from the basic stop strategy Template is "always try to trade next bar against current

position, and do so when stop is hit". So you cannot use the signals (there is a signal every bar), you have to use the actual position of the stop

strategy as the input for your strategy which combines the simpler models. While your stop-based strategies change position inside the bars, the

signals are "known" only at the close. I call such models by the name "Discovery At Close" (DAC) models to remind me of that.

How does this relate to Anti Grail? While it is not motivated by it, it is as you suspect, related. See Steve Ward's post in the tips about "Bizarro".

Example: We know (from reading Market Wizards!) that the Big-Firm floor traders can move prices to hit the stops we just set up in our Turtle-like

template. While they succeed, the equity curve of our stop model suffers a declining trend. But they don't always succeed, or they would be long ago

retired. (Unless they are obsessed, in which case their "size" gets too obvious and cumbersome) So what I try to do with the NST optimizer, is find

what conditions under which their strategy of "running the stops" fails or succeeds. When my equity curve falls, the floor traders are winning, when it

rises, something bigger is overwhelming their little game. That is an example of what I would call a "Strategy". You can try to extract information from

the market prices based on modelling what the traders admit they are looking at when they trade, and rather than blindly following their methods, try

to decide who is winning, and who is losing, and when, and how much. One trend you CAN depend on is that the game goes on and on. The

traders won't stop hitting the ball back and forth.

Referring to the Turtles-style Breakout example, the Strategy Template can mark the STOP PRICE (hypothetically) execution to market equity instead

of the closing price or next bar opening price. The Strategy Wizard puts the red and blue X's right at the stop prices; they are reflected in your trading

statistics you optimize with the optimizer, but you still don't know how many times the actual price crossed the Stop!!!!! Maybe you paid ten times for

just one trade! Really you would need tick data or a trader on the floor. That's probably a decent example of what Trout means when he says his

EXPERIENCE with computer models (in New Market Wizards) is that maybe half his profits are the "edge" from the models, and the other half from

discretionary execution, etc.

Steve

On 7/1/2005 12:26:53 PM josh wrote:
Thanks, Steve.

". . . but a breakout stop-order Template (in trading strategy wizard) . . . is my starting point."

That is a fascinating concept. But- and don't take this the wrong way- by any chance did you arrive at that strategy after repeated attempts to develop a "successful" trading system resulted in developing a wonderfully consistent "losing" trading system? A.k.a. The Un-Holy Grail? The Anti-Grail? I ask because I think I'm closer to cracking that mystery than I am to a decent model. The thought has occurred to me at times that I should be able to safely take the opposite positions of my strategy's signals and do quite well.

If I understand you correctly, your model has the following characteristics:

it relies on "sub-models" for entry conditions
sub-models take the theories of the turtle system (based primarily on the identification of trends) and creates simple entry signals and stops.
the trading model takes the sub-models' stop signals for it's entry signals
you use portfolios of trading models to diversify among issues and time frames

Can't an entry signal using another model's stop signal be instead positively identified with an indicator? Is it easier for one to generate the multiple layer models (for a variety of issues)– necessary to diversify across time– by beginning with a first model that generates stop signals? As you diversify across time, is it your hope/expectation that, although you may lose one or two or five in a row, ultimately you will have a bunch of individually deployed signals ganging up on a trend?

"The simplest stops are . . ."

Oy, vay! As I've stated recently, I'm still a newbie here, so maybe when I butted in asking for specifics, I stepped in it. I still have some larger issues I need to arrive at on my own through trial and error screwing around. I really appreciate your willingness to lay it out like that, Steve.

Marcel, thanks for starting this thread! Hope I haven't steered it too far from your original goal.

Josh

On 6/30/2005 9:59:14 AM Steve Eberbach wrote:
Funny thing, this Synchronicity!

I also am reading "The New Market Wizards", and am getting very pumped. Trading is so complex that it is very difficult for a single person to "do it all" themself. It takes a team of people with various talents working together with psychological diversity and checks and balances, unless you are one of those "multi" types with perfectly disciplined ADHD.

I am grateful to have Steve Ward and Co. on my little team.

You no longer have to buy the original Turtles' strategy to learn it.
Have even been modelling the "Turtle system", which you can read about at:

http://www.originalturtles.org/system.htm

The tough part is the putting-on-positions rules requiring a time/price-diversified staged entry and exit strategy, but it is key, mathematically, to the success, which I have verified to my own satisfaction with NST, using overlaid strategies. (See tips) I have only verified some of the principles involved with "Turtle-like" models.

The real thing is really much more difficult to model and execute than the more typical signal-and-threshold paradigm, but a breakout stop-order Template (in trading strategy wizard) which is [almost] always trying to enter the market OPPOSITE the current position with stop orders is my starting point. The simplest stops are Lag(Max,PriceTimeSeries), spanbars(lagbars) and Lag(Min(PriceTimeSeries) spanbars)lagbars. Just like the original Turtles' "Breakouts". Layer on more copies of basic strategy with stops offset in price to simulate staged entries, exits, reversals. You have to begin by assuming you will Timing-diversify using several contracts, or "lots" of stock shares.

Also key to success is being able to diversify among instruments of trading, because nothing trends all the time, let alone trends all the time in just one direction. It is analogous to catching popcorn just as it is popping. Focussing on each popping kernel one at a time is a frustrating exercise at best.

Steve

On 6/29/2005 9:45:33 AM josh wrote:
'I can understand people's reluctance to . . .'

Agreed.

'An example in the public domain is the turtle trading system . . .'

You may be interested in this. I bought the turtle program a few years ago. In it they extolled the virtues of the trend trading philosophy: citing statistics on trending vs. non-trending periods, the phenomenon of trends showing up in coin flips, etc. (I haven't plugged it into trading system software to test it because I've never learned how to account for changing position size.) But anecdotal evidence suggests those using the system suffered a period back then that wiped many out. Perhaps because there were so many users? I don't know the answer to that. The futures markets entered a non-trending period of sustained duration to the extent that Richard Dennis closed up shop. (He may have reopened as the markets have been looking more trendy in the last year or so)

My gut is that the turtles brought attention to the overall phenomenon of trend following because it was such an easy idea to understand, and that successful models developed with much help from NST would hinge on theories less easily articulated and therefore not mass distributed.

I'm sure you didn't mean it this way, but just to clarify, the Turtle system is not in the public domain, although it might as well be, as you said, "we all know how it works."

Finally, wouldn't it be cool to arrive at a new theory, as easy to understand as "trend following," that revolutionized the risk-management industry? Talking about this makes me want to re-read "The New Market Wizards," almost as good as the first one, but seems more focused on systems traders. Reading that series always gets me pumped.

Josh

Marcel-

I am interested in sharing. There is a quasi-precedent for this practice dating back to 2000-01 among individuals collaborating on a system. Wonder how they got along? Their posts were entertaining to read as they developed criteria for issue selection, objectives to predict, inputs they like, etc. If I had a profitable model I would share it in this post. Alas, I am not working on that skill set yet. Have you ever seen Karate Kid? I'm still at "wax on! wax off!" I.e. working on getting the Prediction Wizard to optimize my inputs and parameters to result in 5 out of 5 profitable walk forwards. Maybe I should ease up on my input criteria before trying to codify trading rules?

Some of the inputs I'm toying with are BBands, stochastics, old highs and lows, as well as Turning Point, Advanced Indicator Sets, Clusters and Fuzzies. In reality, I think there are more than enough indicators included in the program to keep someone new like myself busy for a year or two. I appreciate your suggestion to exclude add-on indicators in shared models.

You alluded to the school of thought that argues against sharing "the total package." (my term) I don't subscribe to that, but like you, I have the upmost respect for those who do. We all know how much work goes into a successful model (more than I've put in!). I simply don't think enough people could copy a strategy and implement a trading program based on it to significantly influence the S/D of highly liquid stocks before the market changes of its own volition rendering the strategy obsolete anyway. So, for me, sharing is merely akin to fleshing out the excellent examples included in the software- something I hope to do for as long as I'm using this product. For others, it may seem like shoothing themselves in the foot.

Josh

On 6/27/2005 11:57:13 AM Marcel wrote:
I know that with this message I'm going to touch "sensitive ground", nevertheless I'm serious about it and wish to explore further.

I ask myself if there would be interest to share Models among members of this forum.

IMHO there are little reasons why not:
- Most of us are using NST for personal rather than corporate interest
- There is only limited IP to be "given away"
- Experience is the essence here, not the results in form of models
- It would be an additional advanced educational enrichment for all of us
- It would help us to relatively compare the quality of our own models
- And generate new idea and ground to work on

From my side I'm willing to share the models I'm trading with. Most of them make use of Jurik indicators, but these can easily be replaced by traditional indicators with some performance decrease to be expected. I'm using EoD data only, not sure if models can be used for Intraday too.

Your thoughts and comments are welcome.
Marcel

Re: Model Sharing

Date :7/14/2005 3:31:32 PM Poster : Marcel

Mark,

I fully agree that the key to a successful model is to master its building process. My call for models was intended to pick it up from the tail: Analyze the models, understand the key success criteria and the development process, discuss alternatives and generalization potential, etc. But I'm perfectly fine by doing it the "forward way".

I have only one little request, to start our discussion pragmatically. The more it evolves, the more we will be able introduce more complex themes and/or advanced paradigms. Why? It's simply to attract more contributors. Most of the forum's visitors are pretty new to NST, and are maybe "afraid" to reply to an article. So let's create a platform where all can contribute, let's keep it simple to start, let's maybe build together a model that everybody can replicate. The discussion will organically evolve as and when more experienced users will add their own points of view, share their knowledge or bring up new ideas.

Mark -- If you allow me, I'm going to start the thread "What needs to be achieved to build a profitable Neural Net?" for you. I will try to briefly document the process that I follow for myself, and hope for many, many replies, critiques and other opinions/processes.

Regards,
Marcel

On 7/11/2005 2:51:17 PM Mark Simpson wrote:
Hi All,

To me, a model is the end result of a process, and that the best
place to start is finding out what needs to be done, then finding/building the tools
to achieve that and then finally ending up with a working model, rather than just
trying to find a working model.

Another way of looking at it is, are we looking to be provided a rod, line and the location, or do we want to learn how to fish?

Models tend to be very specific to peoples risk level, trading timeframes and interests.
An ideal model for one individual probably isn't ideal for another. Also people
tend to have a lot of IP tied up in their models, so are generally unwilling to share
due to the risks involved in doing so. However, people quite often are willing to share
concepts, methods or techniques.

Howabout a discussion starting with "What needs to be achieved to build a profitable
Neural Net"?

Then maybe we could progress into a discussion about the tools/needed. Suggested
items to start with could be:

1. What neural networks can learn, and what they can't learn.
2. Heisenberg, Filters, What is lag. Removing lag, and creating/using
leading indicators.
2. Curve fitting. What it is, how to avoid it and how to use it to advantage.
3. Normalizing Time.

I also, don't want to misdirect this thread. If there's enough interest, then I'll
start the discussion with a "demonstration model" that can be used to figure out
the first question "What needs to be achieved to build a profitable
Neural Net?".

I.e. working on getting the Prediction Wizard to optimize my inputs and parameters to result in 5 out of 5 profitable walk forwards. Maybe I should ease up on my input criteria before trying to codify trading rules?

Some of the inputs I'm toying with are BBands, stochastics, old highs and lows, as well as Turning Point, Advanced Indicator Sets, Clusters and Fuzzies. In reality, I think there are more than enough indicators included in the program to keep someone new like myself busy for a year or two. I appreciate your suggestion to exclude add-on indicators in shared models.

You alluded to the school of thought that argues against sharing "the total package." (my term) I don't subscribe to that, but like you, I have the upmost respect for those who do. We all know how much work goes into a successful model (more than I've put in!). I simply don't think enough people could copy a strategy and implement a trading program based on it to significantly influence the S/D of highly liquid stocks before the market changes of its own volition rendering the strategy obsolete anyway. So, for me, sharing is merely akin to fleshing out the excellent examples included in the software- something I hope to do for as long as I'm using this product. For others, it may seem like shoothing themselves in the foot.

On 6/27/2005 11:57:13 AM Marcel wrote:
I know that with this message I'm going to touch "sensitive ground", nevertheless I'm serious about it and wish to explore further.

I ask myself if there would be interest to share Models among members of this forum.

IMHO there are little reasons why not:
- Most of us are using NST for personal rather than corporate interest
- There is only limited IP to be "given away"
- Experience is the essence here, not the results in form of models
- It would be an additional advanced educational enrichment for all of us
- It would help us to relatively compare the quality of our own models
- And generate new idea and ground to work on

From my side I'm willing to share the models I'm trading with. Most of them make use of Jurik indicators, but these can easily be replaced by traditional indicators with some performance decrease to be expected. I'm using EoD data only, not sure if models can be used for Intraday too.

Your thoughts and comments are welcome.
Marcel

Re: Model Sharing

Date :7/25/2005 7:20:18 PM Poster : Alan Rhodes

And I will be trying to centralize our thoughts into one project plan.

On 7/14/2005 3:31:32 PM Marcel wrote:
Mark,

I fully agree that the key to a successful model is to master its building process. My call for models was intended to pick it up from the tail: Analyze the models, understand the key success criteria and the development process, discuss alternatives and generalization potential, etc. But I'm perfectly fine by doing it the "forward way".

I have only one little request, to start our discussion pragmatically. The more it evolves, the more we will be able introduce more complex themes and/or advanced paradigms. Why? It's simply to attract more contributors. Most of the forum's visitors are pretty new to NST, and are maybe "afraid" to reply to an article. So let's create a platform where all can contribute, let's keep it simple to start, let's maybe build together a model that everybody can replicate. The discussion will organically evolve as and when more experienced users will add their own points of view, share their knowledge or bring up new ideas.

Mark – If you allow me, I'm going to start the thread "What needs to be achieved to build a profitable Neural Net?" for you. I will try to briefly document the process that I follow for myself, and hope for many, many replies, critiques and other opinions/processes.

Regards,
Marcel

On 7/11/2005 2:51:17 PM Mark Simpson wrote:
Hi All,

To me, a model is the end result of a process, and that the best
place to start is finding out what needs to be done, then finding/building the tools
to achieve that and then finally ending up with a working model, rather than just

trying to find a working model.

Another way of looking at it is, are we looking to be provided a rod, line and the location, or do we want to learn how to fish?

Models tend to be very specific to peoples risk level, trading timeframes and interests.
An ideal model for one individual probably isn't ideal for another. Also people
tend to have a lot of IP tied up in their models, so are generally unwilling to share
due to the risks involved in doing so. However, people quite often are willing to share
concepts, methods or techniques.

Howabout a discussion starting with "What needs to be achieved to build a profitable
Neural Net"?

Then maybe we could progress into a discussion about the tools/needed. Suggested
items to start with could be:

1. What neural networks can learn, and what they can't learn.
2. Heisenberg, Filters, What is lag. Removing lag, and creating/using
leading indicators.
2. Curve fitting. What it is, how to avoid it and how to use it to advantage.
3. Normalizing Time.

I also, don't want to misdirect this thread. If there's enough interest, then I'll
start the discussion with a "demonstration model" that can be used to figure out
the first question "What needs to be achieved to build a profitable
Neural Net?".

Regards
Mark Simpson

All,

First of all, thanks for keeping this thread alive while I was away - following Josh's advice (http://www.ward.net/cgi-bin/Forum/Forum_Article.asp?a=2465), I've taken a break to recharge my batteries...

It's very interesting to read all your comments and to assure Josh and Steve, I've absolutely no issues with how this thread is evolving. I fully concur with Steve that the main aim is to SHARE EXPERIENCES, to learn, to avoid costly mistakes, to become better and ultimately be able to exercise some profitable trades.

But I'm also a very pragmatic and practical guy, and I feel like taking the (maybe arrogant) liberty to make a plea:

"Dear experienced users of NST, please share your models, the more the better. You will have the opportunity to see and analyze models of your peers and fine-tune your own ones."

To be straight-forward and direct, I believe we should start to share some successful *.chl files based on UP-TO-DATE DATA. Most of the NST users have in their earlier days probably gone through many of the available examples or templates on CD or posted on the Ward Systems site, only to find out that these were successful for PRECISELY the dates they were posted. If you move forward or backward the (model) dates, their performance drastically drops until becoming negative. If you apply them to other stocks, it simply doesn't work.

So I ask myself:
- How do contemporary models look alike?
- Do they still exist, considering that stocks falling out of "normal trends"
are becoming the norm (2000 bubble, commodity/energy rush)?
- Are my models good enough – or unacceptable for others?

Thanks!
Marcel

On 7/1/2005 6:42:14 PM Steve Eberbach wrote:
Josh:

I do not think you have steered this topic off Marcel's track at all. In fact the track is getting more solid as we build it. We could change its title to

"Sharing Experiences" to include more generality, just as the "New Market Wizards" shared even more important information in the format of

experiences than they did in the form of "models". Marcel himself said experience is the essence from his own viewpoint. I think that is the purpose

behind Steve Ward's creating this fourm as support of the software.

Quoting Monroe Trout from "The New Market Wizards": " ..if we blindly followed the systems we might make half of what we do now. Maybe even less.

I could give 10 CTAs the exact systems we use, and some of them still wouldn't make any money."
Now, a CTA is a pro by definition, running his/her modelling advice as a serious business.

Put that together with the fact that Trout's team of traders trades from MODELS, many of them, just like users of NeuroShell Trader Pro! Make your

own inferences from that! Maybe Trout even uses NST pro and a team of modelling Geeks instructing his Floor traders!

To be repetitive:

Marcel says: "EXPERIENCE is the essence here". More thanks for starting this thread, Marcel!

Really practical, tradable "total packages" will be a complex of "edges", (models which really work) and good money managemant, just as Trout

said. (Unless you don't believe a successful multi-millionaire trader) If you read between the lines in Trout's and others' interviews, we little Traders

have an edge called small size. We can execute our entire position faster!

The edge from any particular trading model will break down if there is too much size being triggered by its signals. (a factoid from the wizards'

combined experience)

To answer Josh's particular questions:

Yes, you understood very well what I was saying, and said it back in your own words even better than I explained it.

Yes, an entry signal using another model's stop can be "identified with an indicator".

An example would be: SUB(position (StopStrategy)), lag1 (position (StopStrategy))

A change in position from hitting the stop generates a indicator spike one bar later. Using an indicator directly to give a signal would work to give a

go or no-go for the next bar, but would not give you exact feedback from stop price for the optimizer through the equity curve, drawdown accumulation,

etc. because of the equity posting delay from only marking price at the close or next bar open to your equity total accumulation.

The example I gave gives a SIGNAL one bar late. The SIGNAL from the basic stop strategy Template is "always try to trade next bar against current

position, and do so when stop is hit". So you cannot use the signals (there is a signal every bar), you have to use the actual position of the stop

strategy as the input for your strategy which combines the simpler models. While your stop-based strategies change position inside the bars, the

signals are "known" only at the close. I call such models by the name "Discovery At Close" (DAC) models to remind me of that.

How does this relate to Anti Grail? While it is not motivated by it, it is as you suspect, related. See Steve Ward's post in the tips about "Bizarro".

Example: We know (from reading Market Wizards!) that the Big-Firm floor traders can move prices to hit the stops we just set up in our Turtle-like

template. While they succeed, the equity curve of our stop model suffers a declining trend. But they don't always succeed, or they would be long ago

retired. (Unless they are obsessed, in which case their "size" gets too obvious and cumbersome) So what I try to do with the NST optimizer, is find

what conditions under which their strategy of "running the stops" fails or succeeds. When my equity curve falls, the floor traders are winning, when it

rises, something bigger is overwhelming their little game. That is an example of what I would call a "Strategy". You can try to extract information from

the market prices based on modelling what the traders admit they are looking at when they trade, and rather than blindly following their methods, try

to decide who is winning, and who is losing, and when, and how much. One trend you CAN depend on is that the game goes on and on. The

traders won't stop hitting the ball back and forth.

Referring to the Turtles-style Breakout example, the Strategy Template can mark the STOP PRICE (hypothetically) execution to market equity instead

of the closing price or next bar opening price. The Strategy Wizard puts the red and blue X's right at the stop prices; they are reflected in your trading

statistics you optimize with the optimizer, but you still don't know how many times the actual price crossed the Stop!!!!! Maybe you paid ten times for

just one trade! Really you would need tick data or a trader on the floor. That's probably a decent example of what Trout means when he says his

EXPERIENCE with computer models (in New Market Wizards) is that maybe half his profits are the "edge" from the models, and the other half from

discretionary execution, etc.

Steve

On 7/1/2005 12:26:53 PM josh wrote:
Thanks, Steve.

" . . . but a breakout stop-order Template (in trading strategy wizard) . . . is my starting point."

That is a fascinating concept. But- and don't take this the wrong way- by any chance did you arrive at that strategy after repeated attempts to develop a "successful" trading system resulted in developing a wonderfully consistent "losing" trading system? A.k.a. The Un-Holy Grail? The Anti-Grail? I ask because I think I'm closer to cracking that mystery than I am to a decent model. The thought has occurred to me at times that I should be able to safely take the opposite positions of my strategy's signals and do quite well.

If I understand you correctly, your model has the following characteristics:

it relies on "sub-models" for entry conditions
sub-models take the theories of the turtle system (based primarily on the identification of trends) and creates simple entry signals and stops.
the trading model takes the sub-models' stop signals for it's entry signals
you use portfolios of trading models to diversify among issues and time frames

Can't an entry signal using another model's stop signal be instead positively identified with an indicator? Is it easier for one to generate the multiple layer models (for a variety of issues)-- necessary to diversify across time-- by beginning with a first model that generates stop signals? As you diversify across time, is it your hope/expectation that, although you may lose one or two or five in a row, ultimately you will have a bunch of individually deployed signals ganging up on a trend?

"The simplest stops are . . ."

Oy, vay! As I've stated recently, I'm still a newbie here, so maybe when I butted in asking for specifics, I stepped in it. I still have some larger issues I need to arrive at on my own through trial and error screwing around. I really appreciate your willingness to lay it out like that, Steve.

Marcel, thanks for starting this thread! Hope I haven't steered it too far from your original goal.

Josh

On 6/30/2005 9:59:14 AM Steve Eberbach wrote:
Funny thing, this Synchronicity!

I also am reading "The New Market Wizards", and am getting very pumped. Trading is so complex that it is very difficult for a single person to "do it all" themself. It takes a team of people with various talents working together with psychological diversity and checks and balances, unless you are one of those "mutts" types with perfectly disciplined ADHD.

I am grateful to have Steve Ward and Co. on my little team.

You no longer have to buy the original Turtles' strategy to learn it.
Have even been modelling the "Turtle system", which you can read about at:

http://www.originalturtles.org/system.htm

The tough part is the putting-on-positions rules requiring a time/price-diversified staged entry and exit strategy, but it is key, mathematically, to the success, which I have verified to my own satisfaction with NST, using

overlaid strategies. (See tips) I have only verified some of the principles involved with "Turtle-like" models.

The real thing is really much more difficult to model and execute than the more typical signal-and-threshold paradigm, but a breakout stop-order Template (in trading strategy wizard) which is [almost] always trying to enter the market OPPOSITE the current position with stop orders is my starting point. The simplest stops are Lag(Max,PriceTimeSeries), spanbars(lagbars) and Lag(Min(PriceTimeSeries) spanbars)lagbars. Just like the original Turtles' "Breakouts". Layer on more copies of basic strategy with stops offset in price to simulate staged entries, exits, reversals. You have to begin by assuming you will Timing-diversify using several contracts, or "lots" of stock shares.

Also key to success is being able to diversify among instruments of trading, because nothing trends all the time, let alone trends all the time in just one direction. It is analogous to catching popcorn just as it is popping. Focussing on each popping kernel one at a time is a frustrating exercise at best.

Steve

On 6/29/2005 9:45:33 AM josh wrote:
'I can understand people's reluctance to . . .'

Agreed.

'An example in the public domain is the turtle trading system . . .'

You may be interested in this. I bought the turtle program a few years ago. In it they extolled the virtues of the trend trading philosophy: citing statistics on trending vs. non-trending periods, the phenomenon of trends showing up in coin flips, etc. (I haven't plugged it into trading system software to test it because I've never learned how to account for changing position size.) But anecdotal evidence suggests those using the system suffered a period back then that wiped many out. Perhaps because there were so many users? I don't know the answer to that. The futures markets entered a non-trending period of sustained duration to the extent that Richard Dennis closed up shop. (He may have reopened as the markets have been looking more trendy in the last year or so)

My gut is that the turtles brought attention to the overall phenomenon of trend following because it was such an easy idea to understand, and that successful models developed with much help from NST would hinge on theories less easily articulated and therefore not mass distributed.

I'm sure you didn't mean it this way, but just to clarify, the Turtle system is not in the public domain, although it might as well be, as you said, "we all know how it works."

Finally, wouldn't it be cool to arrive at a new theory, as easy to understand as "trend following," that revolutionized the risk-management industry? Talking about this makes me want to re-read "The New Market Wizards," almost as good as the first one, but seems more focused on systems traders. Reading that series always gets me pumped.

Josh

On 6/27/2005 5:17:47 PM Maciej wrote:
I can understand people's reluctance to share models particularly as most of these systems represent considerable effort which no one wants to give away. The reality is that its most unlikely that any two of us will trade a given system in exaactly the same way unless it were totally mechanised including the trigger pulling part. An example in the public domain is the turtle trading system - we all know how it works but few of us have the account size or temperament to trade it.

On 6/27/2005 3:24:57 PM josh wrote:
Marcel-

I am interested in sharing. There is a quasi-precedent for this practice dating back to 2000-01 among individuals collaborating on a system. Wonder how they got along? Their posts were entertaining to read as they developed criteria for issue selection, objectives to predict, inputs they like, etc. If I had a profitable model I would share it in this post. Alas, I am not working on that skill set yet. Have you ever seen Karate Kid? I'm still at "wax on! wax off!" Date :7/16/2005 9:15:03 PM Poster : Alan Rhodes

I am not really sure what else there is to add to your topics. You covered the main obstacles we face building trading models.

Since I work in the computer business, I have a different slant on things. Besides understanding concepts, I do feel discussions can be utilized to better analyze what tools can do and can't do. These can be purchased tools and home built tools. Concepts develop the specifications for the tools we need. We also need to know what tools can do to meet those specifications.

I had a former life as a forester before I got a BS in computer science. As a forester, the more the understanding about the place you worked, the better you were. You needed to know about your climiate, your soils, your ... to better understand your ecosystems and how to manage them better (or in reality, not screw them up on along term basis).

The one culture shock I went into computers is that I needed to learn how to deal with black boxes. I knew everything there was to know down to assembly language programming in my first PC. That was no longer true in my second computer. My main goal in much of my job is knowing what a tool can and cannot do. If there is not a tool, my job is to develop specifications to have a tool built.

The H,L,O,C/4 you posted later is a demo of a tool. My trading partner actually went as far to test 6 inputs (though the results were not enough better that I started using that instead of H,L,O,C/4). You sell tools (very useful ones I may add) and donate tools for free on your web site.

For those of us with full time jobs, family, etc. if a solution cannot be built with tools, we are screwed. I am hoping the math behind much of what is done does not need to be understood. I obviously hope so since I am pursuing it. But even in my case, I daydreamed a tool, asked Ward systems if there was any way to do it in NeuroShell, and gave up. But my friend independently thought of the same thing and is programming it. And if my theory is correct, it should serve as an excellent adaptor into your adaptive indicators. So I speak with forked tongue.

Just to clarify, as an analyst, I seek to clarify what needs to be done (as you spell out, reduce lag is one). As a model builder in NeuoroShell, I also seek to know what can be done with things available. I am hoping I do not need to know how those things do it.

Marcel,

Several months ago I posted several links under the Trend Trigger Factor title.

This is a single indicator that can be used under MetaTrader for forex trading. Moreover, I attempted to call attention to both its strength and its weakness as an indicator, and I asked for a programmer for NS to convert the code (which was also provided). In addition, I provided real time charts (at the time) of the indicator in action.

To my surprise, not a single reply was received. I assumed that other people either found the indicator to be worthless, or they used it without posting further progress.

To summarize, I was disappointed to find the lack of response to what I have found to be a very useful indicator. This lack of response has made me a little bit more thick-skinned when it comes to sharing indicators or systems in the forum.

I find this to be quite a personal dissapointment since I have learned quite a bit from others who have also posted in this forum in the past.

Best regards,

Sunny

Sunny:

I have to jump in here, because I intended to take on your proposal.

Anyway, since I have MetaTrader 4, I set out to try this strategy, but quickly discovered that it would not work with MetaTrader4. I went to the MetaTrader Forum, and found discussion saying that the TrendTriggerFactor code has a future leak making it seem to do better than one should expect.

Meanwhile, Trend Trigger Factor was posted on Ward's NST. So I downloaded it and tried it, with dismal results.

I decided to wait until I could run it again on MetaTrader4 , which perhaps can be done now, since the strategy tester in MT4 is now working.

I suppose that I should have announced my progress, or lack thereof, rather than just giving up. Discouraging experience, I suppose is just as important as encouraging experience. In this game, I get more of the latter.

My sincere apologies, Sunny.

Steve

P.S. If I find out anything from MT forum, I will report it, since at least one other member of this forum is interested. Just getting a published strategy which works on one platform translated to another platform is certainly the kind of experience we can share here without offending anybody unethically.

Steve,

As I mentioned before the indicator that I posted will only work with MetaTrader 3.8. I have not seen this indicator yet for MetaTrader 4. MT 3.8 is no longer supported; however, you might be able to get a copy from the Yahoo forum. (I am traveling now until the end of the summer so my copy of MT 3.8 is in my main computer. If you are interested, I can make it available to you in September.)

I have found the indicator to be quite useful in the 4-hour, daily, and weekly charts. (Some programmers in the MT forum like it and others don't.) However, I use it not as a main indicator, but rather I use it as a double check on other indicators.

In addition, I tried the version available in this site for NS; however, the results are quite different and similar to the ones you got. My results in MT 3.8 appear to be better; however, I am unable to program, and for this reason I provided all of the above information since I thought if it works in one platform it should work on another platform.

You can double check the indicator's results by looking at the charts that I posted and comparing them with NS charts. You can see that the results provided in MT 3.8 catch the tops and bottoms quite nicely.

I appreciate in letting me know of your experience with the indicator. (By the way, I have used some of your indicators with good results), and there is no need to apologize. :-) My results are kind of like Thomas Edison's results -- 99% perspiration and 1% inspiration (misquote).

While I have a system which I think is profitable, it is a totally conventional trend reversal system. I want to develop the unconvetional. Mark is getting at how to do the unconventional.

I will be reviewing posts and try to develop what I think is a project plan for developing the unconventional.

On 6/27/2005 11:57:13 AM Marcel wrote:
I know that with this message I'm going to touch "sensitive ground", nevertheless I'm serious about it and wish to explore further.

I ask myself if there would be interest to share Models among members of this forum.

IMHO there are little reasons why not:
- Most of us are using NST for personal rather than corporate interest
- There is only limited IP to be "given away"
- Experience is the essence here, not the results in form of models
- It would be an additional advanced educational enrichment for all of us
- It would help us to relatively compare the quality of our own models
- And generate new idea and ground to work on

From my side I'm willing to share the models I'm trading with. Most of them make use of Jurik indicators, but these can easily be replaced by traditional indicators with some performance decrease to be expected. I'm using EoD data only, not sure if models can be used for Intraday too.

Your thoughts and comments are welcome.
Marcel

eSignal daily stock data
Date :7/8/2005 6:05:54 AM Poster : Phil Greenwood

Is it possible to pull daily data (for stocks) from eSignal? The "Add New eSignal Ticker Symbol" button only appears if you select "Intraday" on the Chart Wizard, and the timescale options don't go up to daily in the drop box.

How can I add symbols for daily data from eSignal?

(This isn't made clear in the help either - and I can't believe I've only just noticed this after using NSDT for a year).

Re: eSignal daily stock data
Date :7/8/2005 1:18:55 PM Poster : Steve Eberbach

One way might be to download intraday data (half hour or even shorter) to an intraday chart, than use NST to create a daily chart FROM that data. You have the advantage then of being able to pull out information such as: when was the high, when was the low? The disadvantage is bigger data files. You could "export" the daily OHLC files daily, and pick the intraday prices apart into other useful "inputs" columns of your own custom daily data files.

Myself, I switched to Tradestation, but they have their own problems. I think soon brokers will offer "free data feeds" for frequent traders, and Steve Ward mentioned that working toward stable data integration is a top priority for Ward Systems, so I am trying to be patient.

Phil,

I use Esignal futures and have no issues adding new symbols. Try adding a future to see if the function is only with futures for new symbols for daily data.

Phil,

In the Tools, Data Sources, Server dialog, do you have the box checked that says "Use server as an end of day data source"?

Simple technique for removing some noise

Date :7/12/2005 10:56:26 AM Poster : Mark Simpson

Hi,

Here is an extremely simple technique to remove some noise in models with sub 1-bar lag that came out of some of my research a few years back

All you do is, if you're using "close" as your series for an indicator, use Average4(Open,High,Low,Close) instead. It works on pretty much anything provided you have liquidity, and provides a higher signal to noise ratio.

On it's own, it's not going to make the difference between a good system and a bad system, however it can help improve profit in a good system.

You can also use Average2(High,Low) as a runner up, if you don't want to use open for some reason.

Over time, dynamics change and sometimes low may have the highest signal to noise ratio, or any of HLC or any average of OHLC (and there is some good modelling in how those dynamics change), however, consistantly OHLC/4 provides the best signal to noise ratio over time, so is beneficial to use as a close proxy.

The chart includes a Cumulative Sum of the Signal To Noise Ratio of the series being tested. Essentially the higher the value, the more consistantly high the signal to noise ratio of the signal is.

Yellow = Average4(O,H,L,C)
Magenta = Average2(H,L)
Green = H
Red = L
Cyan = C

One side question, actually more for Ward Systems. Anytime I try to H+L+O+C/4 as the indicator I am trying to predict, all I ever get is one trade. Is this correct? I can train for maximum correlation, but even that gives strange results since the total out of sample correlation is often higher then any individual work forward tests.

Re: Simple technique for removing some noise

Date :7/21/2005 10:39:31 PM Poster : Alan RHodes

I was half asleep when I posted this and asked a question which I had struggled with a long time ago, and asked it all wrong.

First, there will be no trades since the prediction is always greater then 0. But my main frustration is that the prediction is often just a reflection of the price behavoir, even if predicting 8 days in advance, which is not possible. When using values from the pull down list, I get a normalized net that makes sense.

What needs to be achieved to build a profitable Neural Net?

Date :7/14/2005 3:37:32 PM Poster : Marcel

All,

1. Preamble:

As commented in the previous thread "Model Sharing", this new discussion is intended for ALL users of NST. Beginners should herewith get a chance to verify whether they correctly learned their first steps, experienced users will be able to steer and move the discussion into more specific areas of interest.

2. The background:

Before describing the process, let me portray what I do in the context of NST:
- I trade mainly stocks and some derivatives (options, warrants)
- I trade mainly on US markets, plus some European issues
- I trade both sides, long and short
- Trading is unfortunately only a hobby, therefore no Intraday

I'm currently working with a universe of instruments that include:
- Dow Jones Industrial stocks
- S&P 100 stocks
- Nasdaq 100 stocks
- Euro Stoxx 50 stocks
- SMI stocks
- Some selected currency pairs
- A few commodity and Treasury Notes
In total I've roughly 500 underlying instruments, for which I update daily the End of Day prices.

3. The development process:

a) Idea generation

The motivator can be an article describing a new concept to me, or an older model that I browse through (e.g. one of the examples provided on the CD), or a new indicator I discovered recently, or a colleague that asks me for a specific predictive analysis. But most of the times it's the fact that the current model(s) is not performing the way I expect or does not generate (anymore) the wished signals.

b) Draft creation

I rarely start completely from scratch, I usually take as a template one of the models I have at hand and try to adapt it to the new idea. At this point in time, I use a set of maybe 10 instruments whose charts I know by heart. If I'm trying out a new indicator, I'd simply try to analyze it's efficacy with regards to being an input signal.

My latest models all share the same principle, an enhanced versions of one of the examples provided on the CD (I think it's Example 6). I have 3 NNs that independently deliver signals to a trading strategy, which ultimately decides and produces the short/long signals. No model has the same set of NNs. In one model the 3 NNs take input from different categories of indicators, while in another the 3 NNs use the same indicators, but set in such way that they consider different timings (short/medium/long term). By default I make little usage of optimization, limit the amount of EoD data to 4-5 years and usually define 1 or 2 walk-forward test periods of 6 months.

This stage requires a lot of trial & error: I experiment with those wizard parameters I'm most familiar with, then copy/paste the most relevant statistical results into an excel sheet, try the next parameter, copy/paste, etc. After a while I get a picture of which parameters provide the best results for the sample. I create variations of the models and retain those that look to be the most promising.

c) Model testing

Once I have created what I think is the best set of model variations, I test them with the full set of 500 instruments I've in the database. Depending on the degree of optimization, this can take quite some time, but I tend to discard those model variations that take more than a night to complete – simply not practical.

With regards to the data, I keep a set of EoD data for all instruments frozen for a particular date, usually the weekend before I start the development. The development of a new model may take a few weeks to complete and I want my reference data to be consistent over this period of time.

d) Selection and verification

I will then do a lot of manual copy/paste, recording in an excel sheet the results of those instruments that fulfill the following criteria:
- Out of Sample statistics:
- more than 70% successful trades
- double performance than buy & hold strategy
- yearly performance of at least 30%
- Visual check of Out of Sample chart:
- buy/sell signals placed at the right turning points
- no major mistrades or periods of inactivity in the chart
- no major drawdown

If the above 6 criteria are fulfilled, then the model variation with this particular instrument qualify for what I call "tradable list". In average, I'd be able to produce maybe 5-10 instruments for a particular model variation. If the same instrument is present in more than one model variation, I'd keep only the one that I deem the best.

Note: I'm not completely satisfied with my Selection/verification stage. In a recent thread "Empiric Selection Criteria", I've tried to address some concerns and ask a few questions. I'm currently testing the good hints I got there, but I'm also very interested in other's opinions.

e) Implementation

I don't wait long before starting to trade – I don't have the patience to go through another paper trading phase! I'd start to trade a subset of the new model's instruments right from day one, first by "fooling" the system and buying those instruments which were filled in the past and are negative [that's not a joke, I did it!]. For the others, I'd wait and as and when new signals are produced, I'd go long/short accordingly.

Other considerations relative to Money Management are out of scope here and may be addressed in another thread.

4. The trading process

The daily process is very simple and takes only 15 min: In the morning I update the database with the latest EoD data, and I then open all the models and check for new signals. Trades are placed accordingly with the various brokers.

5. A demonstration model

I'm enclosing one of the models I've produced about 2 month ago, that for the sake of this forum I will call "ForumSample001". [I hope that the WebMaster can create the link for the download here.] The file referenced may be downloaded using the following link:

ForumSample001.zip

The model was trained with data up to 31.5.2005 and produces somehow usable signals. It's not the best I have in my arsenal, but it's one of those that do not need any specific add-ons or licensed indicators. If we share models, I think it's important that we select those that can be used by most users – i.e. no intraday, no add-ons.

It qualified for 6 stocks as well as the US 10Y Treasury Yield. Although I follow them with my watch list, I haven't yet traded them.

Best regards,
Marcel

Re: What needs to be achieved to build a profitable Neural Net?

Date :7/15/2005 12:46:27 PM Poster : Mark Simpson

Hi,

Firstly, "Danger Will Robinson", do not use this example for trading. This example will not produce any realtime valid signals.

Click here to download chart referenced in this post

This chart is designed to illustrate what needs to be achieved to build a conventional profitable neural net using conventional indicators. It demonstrates the effect of lead on an indicator. (i.e. bringing the future forward). The idea being, to figure out what needs to be achieved to build a profitable Neural net.

You take an indicator, lead it by N bars, and predict Percent Change In Open 10 days. Essentially we're calculating the amount of lead we need for a neural net to effectively predict price.

I've picked RSI in the example, but you can replace it with pretty much any regular conventional indicator, i.e. Stochastics, MACD etc., provided you keep around the same number of periods (10).

You can also change the number of periods and retrain the nets, however you'll need to change the lead too. Essentially the longer the periods in the indicator, the more lead you'll have to add. (That equates to lag in a filter).

I've put data for the sp500 in the chart, however you will find it works on pretty much anything that has liquidity and in any timeframe.

I've kept this simple for purposes of example, but I suggest you also convert this into a TDNN (Time Delay Neural Network), to get even better results. (see my previous postings on this).

In summary:

Lead Bars Correlation Percent Profitable Trades Ratio Avg Win/Avg Loss
0 -0.0876 50% 0.11
1 -0.0262 92% 0.63
2 0.179 88.7% 3.71
3 0.315 80% 3.76
4 0.415 85.5% 2.88

You will find from the above results and the chart that at 4 bars lead, the net has learnt very effectively. 332.7% Return on a daily sp500 is good going, all with no optimizing. In practice I find with periods of around 10, that for most indicators, the amount you have to lead by to make obscene profit is about 3-4 bars lag. To just over break even (i.e. you could say the point at which you start making a small amount of profit), is 2 bars.

Most indicators introduce lag, and the lead we're adding is offseting that lag that's been introduced by the indicator (in this case RSI). Therefore, to be profitable, we need to remove (or workaround) lag. In this case we want to remove 3-4 bars of lag.

Because of every trade consists of an entry and exit, we have 3-4 bars of lag we need to remove twice, i.e. for any trade, we need to remove 6-8 bars of lag.

Now we have a template for a system that makes money. Next stage is we need to figure out is how to remove lag. To do this we need to understand some concepts like Heisenberg.

However, there is one REALLY easy way to remove 3-4 of those 6-8 bars immediately, which essentially gets you into that 2 bars on entry and 2 bars on exit area, i.e. "Just Profitable". After that every bar of lag we save will make a huge difference to return.

Ever heard of the saying "Take Your Profits and Run?". If you set small target values as your exit point, then you have "Zero-Lag" on your exit. I.E. You've immediately removed 3-4 bars of lag. (it's wise to set a stop limit at 1/2 your profit).

Personally when I figured the above out, a light bulb switched on for me, and I hope this can help that light bulb switch on for some other people too.

Re: What needs to be achieved to build a profitable Neural Net?

Date :7/18/2005 9:38:14 PM Poster : Mark Simpson

Hi,

I've had a couple of people ask me about TDNN directly, so here's the scoop with an example chart and an image of the process.

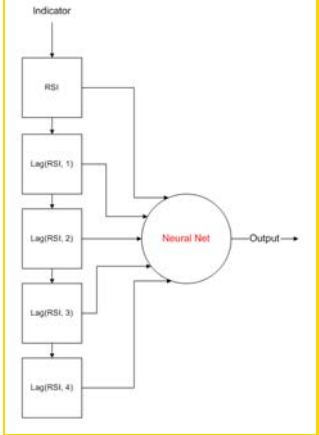
Firstly, here's a test for your complex built in neural network that we were all born with.
The closing price today of ticker XYZ was $65.23. What will price do tomorrow?

See the problem?

We would ask, what did price do the day before, and the day before that,
i.e. I would be looking for a pattern in price. The price on it's own isn't very helpful.

Computer based neural nets are no different. Neural nets have no concept of events over time unless
we build a neural net to incorporate that feature. So feeding say RSI 5 into a neural net makes it difficult for it to learn as it's only one point in time and it has no reference to other points, all it can reference is what it's already learnt about a particular point. E.G. It might learn that an RSI of 80 means sell, but not every RSI of 80 in reallife does mean sell. A pattern of RSI peaking maybe more likely to mean sell than RSI being pegged at 80 for 40 bars for example.

This is where Time Delay Neural Networks (TDNN) come in to play. They provide the ability to recognise patterns in the data being presented, and they're pretty simple.



All that needs to be done is to take your indicator and feed it into the neural net with various lags of the same indicator, e.g.

RSI(5)
Lag(RSI(5),1)
Lag(RSI(5),2)
Lag(RSI(5),3)
Lag(RSI(5),4)

Essentially you're creating a time delay process where on every new bar the previous bars moves down in the list, like people waiting in line.

Now you can recognise patterns in data.

This is the way to achieve it manually in prediction wizard, however there are other ways of achieving the same process. E.G. Ward's Adaptive Net Indicators with their LagPredict feature (highly recommended) . And also, any indicator that recognises a pattern, like the inbuilt candlestick patterns etc.

However there is a price to pay, which is every input you add to a TDNN adds (at least) 1 more degree of freedom (DOF) to your model, which means you will require more trades to test your model and avoid curve fitting.

There is some more information about it in a previous post I made on January 12th 2003.

BTW I'm not advising using a conventional RSI, it's just for purposes of example.

Re: What needs to be achieved to build a profitable Neural Net?

Date :7/20/2005 8:20:35 AM Poster : Marcel

Mark,

The TDNN principle you are introducing here is interesting. I've been experimenting a bit with the example you provided, and I'm afraid I will have to ask a few questions.

a) Can not replicate the exact same NN
Although I've checked and re-checked all the options one can enable/change within the wizard, there is no way I can replicate exactly the same NN. It looks as if there is a hidden option that I can't modify. Any idea why?

b) Reliability
Although trying several different conventional and non-conventional indicators, it seems to me that the NNs are behaving irrationally. Periods where signals are generated consistently are followed by other periods where absolutely no signal is given. This can last 300 bars or more and is usually induced by a change in the long-term trend. Did you observe the same behavior?

c) Applicability
I may have to further experiment, but maybe you can give us a little hint in which context you implement this principle:
- As a standalone NN – or in conjunction with other NNs?
- You are mentioning "not advising using a conventional RSI", which are the indicators you would therefore advise to use?
- How much have you been able to generalize TDNNs, do you see its application for very selected instruments only or can it be broadly used?

Thanks a lot.
Cheers, Marcel

> within the wizard, there is no way I can replicate exactly the same NN.
> It looks as if there is a hidden option that I can't modify. Any idea why?
There are no hidden options. All you do is put:

Lag(RSI(Close,N),0)
Lag(RSI(Close,N),1)
Lag(RSI(Close,N),2)
Lag(RSI(Close,N),3)
Lag(RSI(Close,N),4)

as inputs into a neural net, where N can be anything reasonable.
Of course Lag(RSI(Close,N),0) can be replaced by just plain RSI(close,N) as they are
logically equivalent.

It doesn't have to be 5 inputs, you can detect peaks and valleys with a minimum of 3
inputs.

>b) Reliability
>Although trying several different conventional and non-conventional indicators,
> it seems to me that the NNs are behaving irrationally. Periods where signals
> are generated consistently are followed by other periods where absolutely
> no signal is given. This can last 300 bars or more and is usually induced by
> a change in the long-term trend. Did you observe the same behavior?
Correct. The NN is now learning patterns rather than just values (Overly simplified, because neural nets just see inputs). So if it sees new patterns which it hasn't
learnt on, then it is unable to predict.

c) Applicability
>I may have to further experiment, but maybe you can give us a little hint in
> which context you implement this principle:
>- As a standalone NN – or in conjunction with other NNs?
You could do it as either. However it's only a technique that can be part of
a model. I.E. A model will use many techniques. Any single technique on it's
own will not be profitable, but it's from a combination of techniques that you can
derive a successful model.

>- You are mentioning "not advising using a conventional RSI", which are the
> indicators you would therefore advise to use?
I just wanted to make it clear that this is an example of a technique. It won't
make you money on it's own. However you can combine it with other things to
make money. As to advising on using particular indicators, I don't. Essentially
using an indicator depends on what you are doing, what the needs are, and what
the context is. However, I will be later discussing (if these threads show significant
interest), classes of indicators that work, and why they work, and how to identify
the rest that don't, and maybe a bit about how to fix the ones that don't. However
to identify these classes, these concepts we're discussing now should be understood.
I'm trying to provide a model to build models.

> - How much have you been able to generalize TDNNs, do you see its
> application for very selected instruments only or can it be broadly used?
It can be broadly used as a technique in a good model.

The advantage is that you're giving a NN the ability to recognise patterns (just
like we look for when we look at charts), however the trade off is you have increased
degrees of freedom if you optimize or curve fit by stock selection, so you need
more trades to validate the model to avoid curve fitting.

Re: TDNN: What needs to be achieved to build a profitable Neural Net?

Date :7/21/2005 12:53:11 AM Poster : Alan Rhodes

There is one part of the experiment you had me do with S&P 500 that I stumbled on accidently that opened my eyes. Since you explained it to me, I am going to gossip and explain it to everybody else. I hope you don't mind me gossiping.

I found that an indicator like a moving average had no predictive qualites. In other words, feeding a lead(moving average,4) into a prediction did not make a profitable prediction. I immediately emailed you and went "Huh?"

You gave me a one sentence response that said it all, "The moving average has no context." I thought and realized that means, the more context you provide a neural network, the greater the potential you have. The TDNN is a way to provide more context. And the corollary is the more context you provide, the greater the opportunity for overoptimization.

Re: TDNN: What needs to be achieved to build a profitable Neural Net?

Date :7/21/2005 4:16:40 AM Poster : Marcel

Mark,

Some more comments and questions:

a) Can not replicate the exact same NN
Apologies, my default setting for "Trading rules used to calculate trading statistics" were different from yours, hence the discrepancy in the output.

b) Reliability
> "...now learning patterns rather than just values..."
I understand your reply – looking forward to discover the other building blocks and get the full picture soon.

For the time being, allow me however to maintain a little degree of skepticism. For example, I question the validity of a NN that generates signals in the out of sample period while having been completely quiet (one or a few signals) during the training period.
- Did the NN really learn or is it irrational or random behavior?
- What are the causes that stop/start a NN to generate signals when no new pattern is recognizable on the chart?
- How to validate/discern those phases with useful signals from the impractical ones?

c) Applicability
> "...discuss classes of indicators that work, and those who don't..."
I'm very interested in the above to validate my observations and conclusions, let's put it on the "to do list"...

Regards,
Marcel

> It looks as if there is a hidden option that I can't modify. Any idea why?
There are no hidden options. All you do is put:

Lag(RSI(Close,N),0)
Lag(RSI(Close,N),1)
Lag(RSI(Close,N),2)
Lag(RSI(Close,N),3)
Lag(RSI(Close,N),4)

as inputs into a neural net, where N can be anything reasonable.
Of course Lag(RSI(Close,N),0) can be replaced by just plain RSI(close,N) as they are
logically equivalent.

It doesn't have to be 5 inputs, you can detect peaks and valleys with a minimum of 3
inputs.

>b) Reliability
>Although trying several different conventional and non-conventional indicators,

> are generated consistently are followed by other periods where absolutely
> no signal is given. This can last 300 bars or more and is usually induced by
> a change in the long-term trend. Did you observe the same behavior?
Correct. The NN is now learning patterns rather than just values (Overly simplified, because neural nets just see inputs). So if it sees new patterns which it hasn't
learnt on, then it is unable to predict.

c) Applicability
>I may have to further experiment, but maybe you can give us a little hint in
> which context you implement this principle:
>- As a standalone NN – or in conjunction with other NNs?
You could do it as either. However it's only a technique that can be part of
a model. I.E. A model will use many techniques. Any single technique on it's
own will not be profitable, but it's from a combination of techniques that you can
derive a successful model.

>- You are mentioning "not advising using a conventional RSI", which are the
> indicators you would therefore advise to use?
I just wanted to make it clear that this is an example of a technique. It won't
make you money on it's own. However you can combine it with other things to
make money. As to advising on using particular indicators, I don't. Essentially
using an indicator depends on what you are doing, what the needs are, and what
the context is. However, I will be later discussing (if these threads show significant
interest), classes of indicators that work, and why they work, and how to identify
the rest that don't, and maybe a bit about how to fix the ones that don't. However
to identify these classes, these concepts we're discussing now should be understood.
I'm trying to provide a model to build models.

> - How much have you been able to generalize TDNNs, do you see its
> application for very selected instruments only or can it be broadly used?
It can be broadly used as a technique in a good model.

The advantage is that you're giving a NN the ability to recognise patterns (just
like we look for when we look at charts), however the trade off is you have increased
degrees of freedom if you optimize or curve fit by stock selection, so you need
more trades to validate the model to avoid curve fitting.

Skepticism is always good.

> - Did the NN really learn or is it irrational or random behavior?
This will be addressed by a future topic.

>- What are the causes that stop/start a NN to generate signals when no new pattern is > recognizable on the chart?
Neural nets learn by example, just as we do. Lets do a quick experiment with our
inbuilt neural nets.

Input1 Input2 Output
2 2 4

We know that output is a function of the 2 inputs, lets call Input1 X, and Input2 Y.
So we have a function: f(X,Y)=Output
We have to figure out what the function is.
Now what's the formula that produces the output from the 2 inputs?

You're probably thinking, well that's pretty simple, 2+2=4, or you might come up with
another solution: 2*2=4. But is it correct? We've formed an asumption on just 1
example, so lets try another example.

f(2,3)=4.5

Now we have to reject our original theory as to the function, it doesn't work for this example. So what now?

Well, one approach maybe to provide even more examples, and eventually you
could figure it out. (a mathematician might try a more targetted approached
based on his experience, and feed values like f(0,0) to see what the function does).
Worse case with enough examples you would have a close
enough example to estimate an output value based in it's closeness to one of
your examples.

A neural net is no where near the complexity of your brain, but you can think of it
like a function learning machine. It doesn't try to figure out the function by testing,
it tries to estimate the function by learning by example. I.E. You feed it examples
and the desired result. The neural net runs your example, and compares it's output
to yours. This produces an error, and the neural network is updated slightly and
the process occurs again. Over many iterations of this process, the error between the net and what you are feeding the net for output becomes smaller and smaller, until
you reach a minimum where you are seeing no or minimal improvement.
At this point the net has learnt, and then you can roll it forward on new data.

Now you should be able to see from the above, that the nets ability to learn depends
solely on the quality of the examples. One example, and it won't learn effectively.
Examples all concentrated around certain values it won't learn effectively either.
I.E. We need to provide examples that fully cover the data we intend on
feeding into the net. If you cover the examples space comprehensively then the
net will likely learn well.

Noise also comes into play here, if data is bad, or there isn't a relationship between
input and output, or noise level is high, then you're asking the neural net to learn
something that isn't there. It will dutifully learn the best it can, but the results
won't be useful.

Interestingly enough, it doesn't really matter how complex the function is either, it will
learn it just as effectively too. Also, you can estimate non-linear functions too
because the net contains non-linear activation functions. So what you have in
your lean mean neural machine is just a simple learn by example function estimator.
There's never any function stored in the neural net, it's just the result of error
minimization.

Incidently, the function was: ((X+Y)/2)+2 :-)

The issue for a lot of people (me included when I started off) was that I didn't truely
understand what a neural net was doing. I treated it as a magical black box, which
did things that were truely wonderful, but I wasn't sure how :-). Now I regard
NN's as being dumb functional estimators that depend on clean data with a relationship
being fed to them. Essentially you have to do the leg work first with the inputs/outputs
you're providing. If there is a function there, the neural net will find it, and the
clever part is that it saves you having to figure out the relationship. But the relationship
MUST be there first.

Case in point. (you've probably heard of this before, I don't know if it's folklore
or not, but it illustrates the point). The US Military in the 1st Gulf War, trained a neural
network to visually recognize enemy tanks in the field. When they put it to
use, it didn't work as expected. They did some more testing, they realized that
all the learning examples they'd provided the nets with tanks in were on Sunny days.
The neural net had learnt to detect the difference between a Sunny day and a Cloudy
day, and not if it had a tank in or not.

The solution of course is to provide tanks on sunny and cloudy days whilst learning.
However, what about "Green Fields" or "Desert" and so on?

I recommend if you still see a neural net as a magical black box, that you
go through "Inside Neural Networks" demonstration that's provided with Neuroshell
Trader when you install it (it should be under the Neuroshell Trader category on your
start menu). Study it, and then maybe build your own simple neuron on paper
to experiment with. Learning about how they work gives you a lot of insight
as to what they can and can't do.

Re: What needs to be achieved to build a profitable Neural Net?

Date :7/19/2005 10:28:29 AM Poster : Marcel

Mark,

First of all thank you for mentioning Heisenberg, it gave me the opportunity to spend valuable time going through his biography and principles, and recall remote memories dating over 20 years ago when I was studying quantum physics...

I stepped over the lead() function pretty soon after receiving NST, and after having developed several models that were achieving incredible performance and accuracy, I was obviously delighted believing to have found the perfect model. My joy didn't last long however, my skepticism about the results lead me to discover the flaw. I guess a classical mistake for many beginners, since the issue has been already addressed in several threads.

In simple words, one cannot create a model that relies on future data, that's what the lead() function implicitly does. When you work in real-time, the system won't produce any signals, since future data isn't yet known or available. Signals will be plotted on the chart delayed by exactly X bars (days) later, X being the "periods ahead" specified with the lead() function.

This clarification was for those who may not yet have experienced the negative consequences of the lead() – not for you, Mark. From your article I got the impression that you want us to understand, that there is way to constructively make use of the lead(). I thought "either is Mark miles ahead (Heisenberg?), or I'm missing something here".

For the purpose of this present discussion, I've therefore taken the example and enhanced it so that I can visualize your logic.

Click here to download the chart

a) "Lead 4 – Lagged 4" strategy:

First I created a trading strategy that simulates the worst case, which is "acting upon signals that are generated with a delay of 4 days". Technically speaking, I've added a 4 day lag to the "Lead 4" network. These are the results (original "Lead 4" in brackets):

Annual Return on Trades: -7.20% (83.10%)
Percent Profitable Trades: 33.30% (85.50%)
Ratio Avg Win/Avg Loss: 1.36 (2.88)
Maximum Drawdown: $829.07 ($131.90)

No surprise at all, acting with 4 days delay completely destroys the model – and we haven't yet considered transaction costs!

b) "Lead 4 – Lagged 2" strategy:

Following Mark's comment "there is one REALLY easy way to remove 3-4 of those 6-8 bars immediately" I though – why not see what happens if we hypothetically consider a delay of only 2 days instead of 4. These are the results (original "Lead 4" in brackets):

Annual Return on Trades: 73.80% (83.10%)
Percent Profitable Trades: 97.10% (85.50%)
Ratio Avg Win/Avg Loss: 3.05 (2.88)
Maximum Drawdown: $40.05 ($131.90)

Well, this was a surprise! I thought the statistics would fall somewhere between the fictive case (Lead 4) and the worst case (Lead 4 – Lagged 4), but unless I did a mistake somewhere, the above results are indeed even better than one can hope.

c) "Lead 4 – Lagged 4/2" strategy:

The 3rd strategy intends to come a bit closer to a real case – we enter long/short with a 4 days delay, but exit with a 2 days delay (= average). This to follow Mark's comment "Take Your Profits and Run". These are the results (original "Lead 4" in brackets):

Annual Return on Trades: 30.00% (83.10%)
Percent Profitable Trades: 58.90% (85.50%)
Ratio Avg Win/Avg Loss: 2.09 (2.88)
Maximum Drawdown: $108.38 ($131.90)

Annual return is down substantially, but depending on one's targets it can still be in the range. Profitable trades are still above 50%, but may be insufficient for some. Drawdown seems good. The above does not yet take into account transaction costs, which may jeopardize the displayed results. Considering a fix traded amount of $10'000 and costs of $30 per trade, we get (original "Lead 4" in brackets):

Annual Return on Trades: 15.50% (83.10%)
Percent Profitable Trades: 47.80% (85.50%)
Ratio Avg Win/Avg Loss: 1.85 (2.88)
Maximum Drawdown: $920.77 (N/A)

At this point, the light bulb hasn't yet switched on for me! Some simple questions arise:

- Is there a clever tactic that would allow us to come closer to the strategy "Lead 4 – Lagged 2" above?

- We may be able to anticipate exits (e.g "Take Your Profits and Run"), but what about the entries?

- Is there a way to systematically implement the "Take Your Profits and Run" approach – maybe trailing stop losses?

- The example makes use of a simple RSI, what about all the effort we put in fine tuning our indicators?

- Does this introduce the paradigm that (in the end) indicators are irrelevant, they all have the same effect?

I hope we can continue this discussion, maybe with the contribution of other readers...
Regards, Marcel

P.S.: My apologies a) for another long article, b) to those readers that find the above boring, but the intention is to build up the discussion from the basics, advanced matters will follow soon...

On 7/15/2005 12:46:27 PM Mark Simpson wrote:
Hi,

Firstly, "Danger Will Robinson", do not use this example for trading. This example
will not produce any realtime valid signals.

Click here to download chart referenced in this post

This chart is designed to illustrate what needs to be achieved to build a
conventional profitable neural net using conventional indicators.
It demonstrates the effect of lead on an indicator. (i.e.
bringing the future forward). The idea being, to figure out what needs to be
achieved to build a profitable Neural net.

You take an indicator, lead it by N bars, and predict Percent Change In Open 10
days. Essentially we're calculating the amount of lead we need for a neural net

to effectively predict price.

I've picked RSI in the example, but you can replace it with pretty much
any regular conventional indicator, i.e. Stochastics, MACD etc., provided you
keep around the same number of periods (10).

You can also change the number of periods and retrain the nets, however you'll
need to change the lead too. Essentially the longer the periods in the indicator, the
more lead you'll have to add. (That equates to lag in a filter).

I've put data for the sp500 in the chart, however you will find it works on pretty much
anything that has liquidity and in any timeframe.

I've kept this simple for purposes of example, but I suggest you also convert this into
a TDNN (Time Delay Neural Network), to get even better results. (see my previous postings on this).

In summary:

Lead Bars Correlation Percent Profitable Trades Ratio Avg Win/Avg Loss
0 -0.0876 50% 0.11
1 -0.0262 92% 0.63
2 0.179 88.7% 3.71
3 0.315 80% 3.76
4 0.415 85.5% 2.88

You will find from the above results and the chart that at 4 bars lead, the net
has learnt very effectively. 332.7% Return on a daily sp500 is good going, all
with no optimizing. In practice I find with periods of around 10, that for most
indicators, the amount you have to lead by to make obscene profit is about
3-4 bars lag. To just over break even (i.e. you could say the point at which
you start making a small amount of profit), is 2 bars.

Most indicators introduce lag, and the lead we're adding is offseting that lag that's been
introduced by the indicator (in this case RSI). Therefore, to be profitable, we
need to remove (or workaround) lag. In this case we want to remove 3-4 bars of lag.

Because of every trade consists of an entry and exit, we have 3-4 bars of lag
we need to remove twice, i.e. for any trade, we need to remove 6-8 bars of lag.

Now we have a template for a system that makes money. Next stage is we need
to figure out is how to remove lag. To do this we need to understand some concepts
like Heisenberg.

However, there is one REALLY easy way to remove 3-4 of those 6-8 bars immediately,
which essentially gets you into that 2 bars on entry and 2 bars on exit area, i.e.
"Just Profitable". After that every bar of lag we save will make a huge difference
to return.

Ever heard of the saying "Take Your Profits and Run?". If you set small target values
as your exit point, then you have "Zero-Lag" on your exit. I.E. You've immediately
removed 3-4 bars of lag. (it's wise to set a stop limit at 1/2 your profit).

Personally when I figured the above out, a light bulb switched on for me, and I hope
this can help that light bulb switch on for some other people too.

Comments?

That is correct. Never use lead (or anything else which brings the future forward)
for trading purposes. I've seen many models in the past where people do exactly
that. Fortunately in NST it quite often shows up as "no prediction" for the most
recent few bars, so if you ever see this in any of your models, alarm bells should
immediately ring.

However, that wasn't what I was trying convery in the example model I provided. As
I'm a concerned that I might have not expressed myself clearly enough, lets try
again with a slightly different approach. I'll answer your questions in this post,
and provide a different approach in the next post.

>This clarification was for those who may not yet have experienced the negative >consequences of the lead() – not for you, Mark. From your article I got the impression >that you want us to understand, that there is way to constructively make use of the >lead(). I thought "either is Mark miles ahead (Heisenberg?), or I'm missing something >here".
No, there is no way I know of to constructively lead on it's own in a model in real life.
However in this instance, I'm using it to build a simulation. By doing a simulation
first, you can identify what needs to be done to make something
profitable.

>Following Mark's comment "there is one REALLY easy way to remove 3-4 of those 6-8 >bars immediately" I though – why not see what happens if we hypothetically consider a >delay of only 2 days instead of 4. These are the results (original "Lead 4" in brackets):

This is the breakeven case I was discussing, the 2 bars you are refering to is 2 bars on
entry and 2 bars on exit, =4 bars of lag removed from the 6-8. This is the just
over breakeven point. I.E. With reasonable transaction costs you should be just making
money.

>At this point, the light bulb hasn't yet switched on for me! Some simple questions
>- Is there a clever tactic that would allow us to come closer to the strategy "Lead 4 – >Lagged 2" above?
Yes, using your approach it would be Lead 4 - Lagged 4 on entry and lag 0 on exit.
I.E. Use your regular short term prediction method (which should have around
4 bars of lag already in there), then use take your profits and run to exit (which is
0 lag).

> We may be able to anticipate exits (e.g "Take Your Profits and Run"), but what about >the entries?
Entry techniques and Heisenberg I'll disciss later if there's enough interest in these
threads. So come on all you lurkers out there, respond. Do you understand the concept, do you not.? :-)

>- Is there a way to systematically implement the "Take Your Profits and Run" approach >– maybe trailing stop losses?
yes, profit targets. Pick your entry price and say add "1-2%" to it. That becomes
your exit price. Because you know the exit price now at time of entry, you have a
0 lag exit.

(it would be prudent to put a stop order in at say 1/2 your profit target)

> The example makes use of a simple RSI, what about all the effort we put in fine tuning >our indicators?
Good question. I used RSI because most people understand it. And ironically
you will find (for this simulation) most indicators will work. That illustrates the power
of a neural net. Essentially a neural net can learn most functions if you provide it
the variables input to the function, the output you expect from the function and
enough examples. An RSI is just a calculation on price, so is stochastics, and the
majority of indicators out there. So it's largely irrelevant which indicator you use
for the simulation.

>- Does this introduce the paradigm that (in the end) indicators are irrelevant, they all >have the same effect?
Depends on your thinking. To me, the majority of indicators are redundant, unless
you are feeding them leading information. There are a few exceptions however,
and sometimes you can use a conventional indicator in a non-conventional way.
However, neural nets can reproduce almost
any indicator you wish. Infact maybe we should do that as an example later, teach
a NN to learn RSI.
The trick is in understanding the concepts so that you can immediately look at the
latest indicator and say, "This wouldn't work", or "This works".

A true oscillating momentum indicator, since it is the first derivative of the signal, should lead, with the resulting loss of accuracy (Heisinburg at work). Smoothing it by front loading it (Martin Pring's KST) or whatever magic Jurik does should not affect the leading. So one way of reducing lag is by mixing a good oscillator with a lagging but darn close indicator, such as Jurik's.

Re: Take 2: What needs to be achieved to build a profitable Neural Net?

Date :7/19/2005 9:16:35 PM Poster : Mark Simpson

Hi,

Firstly if you're starting off here, please read my earlier postings in this thread first.

Take 2: So let's start off with a theory:

Yesterday you had a eureka moment and designed the perfect indicator, using
the inbuilt Neuroshell functionality.
You tested the indicator, you'd done everything correctly and hadn't cheated by
putting some element of the future into your perfect indicator (lets call it PI).

PI is clever. It tells you in advance when to enter and when to exit a trade. However,
it's a bit difficult to eyeball, so you feed it into a neural net and it gets it right 90% of the time, and you know now that you can retire in a year.

Firstly, most of you know by now it's not that simple. So what I'm proposing here
is a change in thinking. Conventional thinking produces conventional results, and
we know that conventional results don't work. NST is a very powerful platform that
can be used conventionally or unconventionally, and the option is yours.
(with many other platforms, you're forced into a conventional approach by the
design limitations).

Conventional thinking is that you start off by finding an indicator (maybe out
of NST, TASC etc.), and pop it into NST, test a bunch of securities against it,
and find some that make money. (then generally after testing it in realtime, you
find that it no longer makes money). Even worse, some of the examples that
are printed with the magazine etc. show the indicators working, but when we try them in reallife, we find they don't signal as well as they should. So back to the drawing board, we now find the next wizzy indicator and try again, and so on.
This is how almost every technical analyst using NST (and most other packages) starts, and you could think of it as a right of passage.

So, the question is, what is wrong with the conventional thinking, why doesn't it
generally work? Are the indicators broke? Is technical analysis folly? Or is it our thinking?

Are the indicators broke? Not exactly. We know they work, but we also know
there's something wrong with most of them. They do exactly what they're supposed
to do, but in the process they add lag. And it's the lag that catches us out.
Essentially we're late to the party, and we leave late too, all due to lag. So
at best, we make a little bit of money on a long trend (because we're
late in and late out we don't catch the whole trend), and then we
get whipsawed out in sideways motion which generally eats up any profit we
made in the trend. Add on transaction costs and we're beat.

Is technical analysis folly? Though people have probably told you before that
technical analysis is folly, (hey there was even a few books written about), it's difficult
to ignore cause and effect. Essentially price is reflection of a peoples actions, i.e. it's
an effect.

Cause is the people themselves, each person is an individual, some will
look at fundamentals, some technicals, some will be trading weekly, some daily,
some intraday. Some will be looking for certain patterns to buy, some will be looking to fake by selling those same patterns. And so on. I.E. It's one complex model.
However at certain points in time, things will line up to push price in one direction
or another, and at other points, all the individuals are in conflict and price will
go sideways.

So which is it better to model, the cause or the effect? Effect lags cause, we
know that already. However the inputs we have to our models are price based (i.e.
based on the effect). Are we doomed? Can we model the cause?

So what's wrong with our thinking?
The process is wrong. To make a profitable model that stands the test of time we
really need to start out by figuring out what we are trying to achieve, before figuring
out how to achieve it. We know we need to model the cause but we only have the effect to work with (price), and that it lags the cause.
So hence this is where the demonstration model posted earlier in this thread comes in.

Lets try that different approach to an explanation:

Back to our Perfect Indicator. So, how do you make one of these "Perfect Indicators"?
Well, there's a number of issues that need to be solved first and we will
discuss later (if there's enough particpation). In reality there are physical
limitations which mean you can't get a perfect
indicator, but you can get say a "Near Perfect Indicator", and a Near Perfect Indicator
could be pretty darned good.

So in the meantime, lets simulate our perfect indicator. This simulation is just that,
it's a cheat, we couldn't use it in realtime. But we're trying to find out what we need
to achieve to build it, we're not going to use it to trade anyway.
We know that 99% of the indicators out there lag price and that if they didn't we
could consistantly make money. So lets see how much money we could
make, by cheating and leading price. In doing this we can learn some
useful things.

We know that lead is the opposite of lag, and we know our indicators have lag, so
for the purposes of simulation only (we can't do this in real life), we will lead to
counteract the lag inbuilt in the indicators we're using.

So we start off by looking into the future. I.E. We lead price by 1 bar, feed it to
RSI and then onto a neural net.

Every trade consists of an entry and exit, therefore we have lead by 1 bar on entry
and 1 bar on exit. We run the neural net, and it doesn't lose as much as it
did without lead, but we're not making money yet.

So we add another bar of lead onto it, so now we have 2 bars of lead on entry and 2 bars
of lead on exit. Total 4 bars. Now we just break over even with transaction costs.
Things are good, we know that if we could save a total of 4 bars of lag, we could
start making money, which is good enough for most people.

Now we're getting greedy, so we add another bar of lead. We now have 3 bars of
lead on entry and 3 bars on exit. Total 6 bars. We run it, and the net makes
obscene amounts of money (pity it's only a simulation).

So finally we say, what would happen with 4 bars of lead. (8 in total), and the net
performs better than our wildest dreams.

So from this example we have learnt what we need to do to make money. Obviously the
hard part is doing it and an indepth understanding about lag is needed. However
the simulation is easy to build and demonstrates the concepts.

However, there is one really quick and easy way to get to that "better than breakeven
point", which will work even with conventional thinking and conventional indicators. That
is setting a target based on entry, or "Targetting Small Amounts, and taking your
profits and running".

If you take an entry price, and say at entry, I wish to make 1-2%, i.e. a small amount,
but I wish to make that small amount consistantly, then at entry, you know your exit
point, I.E. If I enter at $100 I know my exit is at $102. Because I know the value
I'm exiting at, then when it reaches that value, I exit immediately. This is a 0 lag
exit (assuming you're in something liquid and have good reaction speeds, or have set
an order to exit). It's 0 lag because you know ahead of time when you're getting out.
(however it's not leading, because you haven't got there yet :-))

So, now lets see how much lag we've saved from our model. The entry still
has 4 bars of lag from the indicator we've been using. However the exit is now 0.
We've reduced our 8 bars of lag to 4, extremely easily with no special indicators
or anything really clever, it's just a simple concept we've used.

Now for the best part. We have the exits beat, for every additional bar of lag we
can save on the entry, will make vast increases to the profit we can reap from
the model.

However, reducing those 4 remaining bars is not easy, and the cost to pay is
accuracy. So it becomes a trade off. If you save 1 or 2 bars, you haven't reached
the theoretical limit, but it would be more than good enough.

If you're a lurker out there, I encourage you to post. Feedback about things
understood or not understood can be clarified and we can learn from the
contributions of others. One of the problems with what we do is that there
are few of our friends/family that understand, and many who are not interested.
This is the only place we can get together and talk about techniques for using
the product we love. Those that are new, ask for help, those who are experienced,
well it's payback time :-) Sunny (who has a lot to share) was reluctant to share
his models/indicators because of a lack of response to a model he posted,
and Marcel has been doing a sterling job of drumming up activity. (I'll get
off my soapbox now :-))

Re: Take 2: What needs to be achieved to build a profitable Neural Net?

Date :7/20/2005 11:51:14 AM Poster : Steve Eberbach

Important quote from last Post:

really need to start out by figuring out what we are trying to achieve, before figuring
out how to achieve it. We know we need to model the cause but we only have the effect to work with (price), and that it lags the cause.>

In my opinion, this is the most important factor, based on my experience.
I have long used the "Perfect" benchmark: cumulative sum of absolute value of all changes in price close-to-close. I also use the cumulative sum of all changes in the natural log, multiplied by 100. This translates into cumulative return in percentage, with the benefit that up and down movements to the same price result in zero percent cumulative return, while using percent change does not.

But is this what we are really trying to achieve? I would say NO, if constraints added to this "perfect fitness" causes a remainder (part of this perfect gain) to be predictable on a more stable basis out of the training sample set!!!!

For this reason, I have long asked Steve Ward to allow access to the ability of setting constraints to the fitness criteria defined in GeneHunter (which is part of Neuroshell Day Trader Pro) Maybe he could consider this for the next (5.0) release. He might consider a license to GH and interfaceto NST as an addon module, also.

A second important principle, in my experience, is that it is best to achieve a small part of the perfect gain with each simple model, and magnify total gain by combining the simple models, as opposed to trying to get one model to do all the different jobs at once. That dovetails with the quote from Mark. We are trying to achieve consistent out of sample gain, not just gain, and achieve it by combining simpler models each of which works better out of sample because constraints were applied to reduce degrees of freedom and irrelevant noise and direct each model to focus on specific contributions to be combined as a team for more consistent success in trading.

To summarize, the definition of what we are trying to achieve is even more important than the definition of the input data, or how they interact in a system. (whether it is achieving "targets", "fitness", or constraints on them.) That is because we have to start with (define) the desired effect, before we can search for ANY cause!

On 7/19/2005 9:16:35 PM Mark Simpson wrote:
Hi,

Firstly if you're starting off here, please read my earlier postings in this thread first.

Take 2: So let's start off with a theory:

Yesterday you had a eureka moment and designed the perfect indicator, using
the inbuilt Neuroshell functionality.
You tested the indicator, you'd done everything correctly and hadn't cheated by
putting some element of the future into your perfect indicator (lets call it PI).

PI is clever. It tells you in advance when to enter and when to exit a trade. However,
it's a bit difficult to eyeball, so you feed it into a neural net and it gets it right 90% of the time, and you know now that you can retire in a year.

Firstly, most of you know by now it's not that simple. So what I'm proposing here
is a change in thinking. Conventional thinking produces conventional results, and
we know that conventional results don't work. NST is a very powerful platform that
can be used conventionally or unconventionally, and the option is yours.
(with many other platforms, you're forced into a conventional approach by the
design limitations).

Conventional thinking is that you start off by finding an indicator (maybe out
of NST, TASC etc.), and pop it into NST, test a bunch of securities against it,
and find some that make money. (then generally after testing it in realtime, you
find that it no longer makes money). Even worse, some of the examples that
are printed with the magazine etc. show the indicators working, but when we try them in reallife, we find they don't signal as well as they should. So back to the drawing board, we now find the next wizzy indicator and try again, and so on.
This is how almost every technical analyst using NST (and most other packages) starts, and you could think of it as a right of passage.

So, the question is, what is wrong with the conventional thinking, why doesn't it
generally work? Are the indicators broke? Is technical analysis folly? Or is it our thinking?

Are the indicators broke? Not exactly. We know they work, but we also know
there's something wrong with most of them. They do exactly what they're supposed
to do, but in the process they add lag. And it's the lag that catches us out.
Essentially we're late to the party, and we leave late too, all due to lag. So
at best, we make a little bit of money on a long trend (because we're
late in and late out we don't catch the whole trend), and then we
get whipsawed out in sideways motion which generally eats up any profit we
made in the trend. Add on transaction costs and we're beat.

Is technical analysis folly? Though people have probably told you before that
technical analysis is folly, (hey there was even a few books written about), it's difficult
to ignore cause and effect. Essentially price is reflection of a peoples actions, i.e. it's
an effect.

Cause is the people themselves, each person is an individual, some will
look at fundamentals, some technicals, some will be trading weekly, some daily,
some intraday. Some will be looking for certain patterns to buy, some will be looking to fake by selling those same patterns. And so on. I.E. It's one complex model.
However at certain points in time, things will line up to push price in one direction
or another, and at other points, all the individuals are in conflict and price will
go sideways.

So which is it better to model, the cause or the effect? Effect lags cause, we
know that already. However the inputs we have to our models are price based (i.e.
based on the effect). Are we doomed? Can we model the cause?

So what's wrong with our thinking?
The process is wrong. To make a profitable model that stands the test of time we really need to start out by figuring out what we are trying to achieve, before figuring out how to achieve it. We know we need to model the cause but we only have the effect to work with (price), and that it lags the cause. So hence this is where the demonstration model posted earlier in this thread comes in.

Lets try that different approach to an explanation:

Back to our Perfect Indicator. So, how do you make one of these "Perfect Indicators"? Well, there's a number of issues that need to be solved first and we will discuss later (if there's enough particpation). In reality there are physical limitations which mean you can't get a perfect indicator, but you can get say a "Near Perfect Indicator", and a Near Perfect Indicator could be pretty darned good.

So in the meantime, lets simulate our perfect indicator. This simulation is just that, it's a cheat, we couldn't use it in realtime. But we're trying to find out what we need to achieve to build it, we're not going to use it to trade anyway.
We know that 99% of the indicators out there lag price and that if they didn't we could consistantly make money. So lets see how much money we could make, by cheating and leading price. In doing this we can learn some useful things.

We know that lead is the opposite of lag, and we know our indicators have lag, so for the purposes of simulation only (we can't do this in real life), we will lead to counteract the lag inbuilt in the indicators we're using.

So we start off by looking into the future. I.E. We lead price by 1 bar, feed it to RSI and then onto a neural net.

Every trade consists of an entry and exit, therefore we have lead by 1 bar on entry and 1 bar on exit. We run the neural net, and it doesn't lose as much as it did without lead, but we're not making money yet.

So we add another bar of lead onto it, so now we have 2 bars of lead on entry and 2 bars of lead on exit. Total 4 bars. Now we just break over even with transaction costs. Things are good, we know that if we could save a total of 4 bars of lag, we could start making money, which is good enough for most people.

Now we're getting greedy, so we add another bar of lead. We now have 3 bars of lead on entry and 3 bars on exit. Total 6 bars. We run it, and the net makes obscene amounts of money (pity it's only a simulation).

So finally we say, what would happen with 4 bars of lead. (8 in total), and the net performs better than our wildest dreams.

Re: Take 2: What needs to be achieved to build a profitable Neural Net?

Date :7/21/2005 12:21:51 PM Poster : Marcel

Mark,

Some thoughts regarding your paragraph: "If you take an entry price, and say at entry, I wish to make 1-2%, i.e. a small amount, but I wish to make that small amount consistantly, then at entry, you know your exit point. I.E. If I enter at $100 I know my exit is at $102. Because I know the value I'm exiting at, then when it reaches that value, I exit immediately. This is a 0 lag exit (assuming you're in something liquid and have good reaction speeds, or have set an order to exit). It's 0 lag because you know ahead of time when you're getting out. (however it's not leading, because you haven't got there yet :-))"

The above is in my opinion correct only if amended by a few important considerations. Yes, for our exits we can set smaller and more predictive targets. But we know that there are no perfect exits:

a) Mistrades
We still incur the risk of entering mistrades, where sooner or later we might have to take our losses. With smaller targets, our protective stops have to be set proportionally closer to our entry price. The probability that these will be hit is higher, and the effect on our performance may be negative too. It's a question of how much drawdown are we prepared to tolerate and how can we minimize it.

b) Type of trend
The strengths and duration of the trend that we try to capture with our trade is a determinant factor. In other words, if we sit on the right side of a long and strong move, the few bars of lag for the exit signal may become marginal – in dollar terms much smaller than the missed opportunity of staying in the trend till the end. Where it kills us is with small or sideways price moves. The question here is whether we can develop the capability of determining the type of trend and choose our strategy accordingly.

So, whether our exit is voluntary (set by target = 0 lag), involuntary (triggered by signal = X lag) or stopped out (loss), we may have to discuss whether there are techniques to reduce lags. Next to the entry lag, under certain conditions we may still want to accept an exit lag.

Regards, Marcel

Correct.

>a) Mistrades

Correct.

>With smaller targets, our protective stops have to be set proportionally closer to our >entry price. The probability that these will be hit is higher, and the effect on our >performance may be negative too. It's a question of how much drawdown are we >prepared to tolerate and how can we minimize it.

A conventional approach would suggest that a protective stop should be set less than the target. And stop management is not an area that should be ignored or taken lightly. However another way of looking at stop management is from a risk perspective. Markets are risky, and risk needs to be mitigated. There are various ways of mitigating risk, and not all of them involve using a stop order.

So the question doesn't become what value we should be setting our stop too. It is really about, how risky is our model. I.E. If you had a perfect model that got it right 100% of the time, then you have 0 risk and you could trade with confidence and wouldn't need a stop order. If you have a model that is 50% successful, then you really need to have your stop set to be half your target if you want to make money. (because you have to consider things like slipage, trading costs etc.)

Put another way, we know that 100% isn't realistically achievable, but maybe 80-90% is (based on us getting close to the results we simulated earlier in this post). Would we need a very close stop order, or could we afford to move it out further?

> b) Type of trend
> The strengths and duration of the trend that we try to capture with our trade

>The question here is whether we can develop the capability of determining
> the type of trend and choose our strategy accordingly.
Correct. Many people can make money trend following with lagging entries and exits, provided:

1. The trend continues long enough
2. Their trend detection system detects trend effectively with minimal lag.

But what happens in reality it that they normally get in late on the beginning of the trend, and out late on the end (because their trend detection system has lag).
Sometimes this will wipe out their profits, sometimes they'll make a bit of money. But they normally go ahead and trade the sideways periods (because the trend detection system mistaken trades sideway motion occasionally) which wipes out the money they made on the trend, because when trading sideways they're late on entry/exit, plus there wasn't any longterm trend for them to make money on.

Bottom line is, that a trend is a trend after the fact. Anybody can look at a chart and spot a trend historically. However as price is effect, if you're looking at price to spot the trend, you're going to be late to the party everytime.

So, how would we make a trend following system more effective? By picking a target for exit and avoiding that lag on exit. At least then we're late to the party, but we leave early and don't have to cleanup afterwards.
By definition a trend will last a while, and it makes money, so why risk that money by being greedy (and trying to always get out at the top, which really is just folly, because lag gets you). If you know it will last a while, then targetting a small amount that you can be sure to consistantly get is better (in my opinion), than waiting for the big fish for a meal, and starving inbetween meals because we're ignoring the little fish that are swimming past and saying, "Hey, eat me".

>So, whether our exit is voluntary (set by target = 0 lag), involuntary (triggered by
> signal = X lag) or stopped out (loss), we may have to discuss whether there
> are techniques to reduce lags. Next to the entry lag, under certain conditions
> we may still want to accept an exit lag.

Personally I would want to see 0 lag on entry and 0 lag on exit, because I know with
this setup (from the simulation), that we would consistantly make money, so I can't
see a situation where having lag on entry or exit would benefit us.
Logic dictates that we
can never achieve 0 lag combined on entry and exit with 100% successful trades.
But to reduce that lag, we need to figure out exactly what lag is first (there are infact
multiple sources of lag) which we'll get into later.
So I see true 0 lag (on both ends) as a theoretical limit, that we can approach but
never reach completely (like infinity).

Re: Take 2: What needs to be achieved to build a profitable Neural Net?

Date :7/23/2005 10:51:47 PM Poster : Steve K

Hi Mark,

I am just getting caught up on the forum posts. Really great stuff you are posting. It got me thinking. The only consistently profitable NN I could build used futures in conjunction with securities data. Basically dumping a bunch of indicators into the NN for the stock and the Futures, then see which ones the GA selected. I think the regression indicators worked well. Kinda crude, brute force approach but it only worked well when the futures were thrown into the mix as a leading indicator

I wonder how many bars of lag ya could remove by using these inputs:

Lag(RSI(Close,N),0)
Lag(RSI(Close,N),1)
Lag(RSI(Close,N),2)
Lag(RSI(Close,N),3)
Lag(RSI(Close,N),4)

along with the same inputs for the NQ contracts and let the NN sort out the correlations.

This would probably work best on shorter time frames where the futures lead is more pronounced. Of course not all stocks move with futures however many do. Also, maintaining the NQ data is tricky cause they expire every 3 mos. A possible substitute could be the compx, the QQQQ or even another stock.

Just a thought, I'll play around with it tomorrow -- but u had some really great ideas, I'll have to read thru them some more -- great thread

Sounds like a plan that would work. You could also use serial correlation of
both items, or say Z-Score both and do some kind of comparison (in simplest form, one
minus the other), and then do the TDNN too.

>This would probably work best on shorter time frames where the futures lead is

You can also make continuous contracts for futures and options (if your data provider
doesn't do them for you, many do) out of a number of different series.

Re: What needs to be achieved to build a profitable Neural Net?

Date :7/16/2005 5:04:30 PM Poster : John

Marcel,

than you for leading this initiative. I am hoping this will get me on the right track after many false starts and poor models that perform well with historic data but which are dreadful going forward.

The issue raised regarding the need for more up to date examples is well made with the canned examples having little transferability in either time or to other instruments. I did not expect these to be magic bullets but hoped the principles would be a little more robust to give me a more confident base on which to build systematically rather than (for me) more random trial and error.

In fact systematic model development is for me a critical goal and one this initiative will hopefully stimulate - with other's approaches to model building being as important as model sharing.

I also need some help. I am having difficulties with the chart you posted - I've done something wrong but I am getting too close to the problem to see the solution.

Could you explain how to get the data into the chart. I opened the zip file and fired up the chart, NST performed an auto search for the data at my request for each instrument and then fired up an abortive e-signal download request for each instrument. The chart loads but has no data. I subsequently copied the expanded folder into my NST folder and manually selected each of the instruments. Still no joy.

Any guidance would be welcome.

Thanks and regards

John

Re: What needs to be achieved to build a profitable Neural Net?

Date :7/18/2005 4:20:15 AM Poster : Marcel

John,

Wrt installing the sample, I believe you have to do the following:
- Unzip the chl-file to a new chart subdirectory
(e.g. NeuroShell Trader 4\chart\ForumSample001)
- Unzip the txt-files to a new data subdirectory
(e.g. NeuroShell Trader 4\data\ForumSample001)
- Start NST, go to Tools -> Data Sources and add the data
directory you created above, assigning a Category of your choice
(e.g. Miscellaneous Instruments)
- Now open the chart, if prompted for automatic load, skip it and
attach the instruments with Format -> Add/Remove Chart Pages

I however discovered a mistake on my side: The sample I included needs a few Jurik indicators – my apologies for that! I thought to have put this model aside because it was NOT using Jurik's indicators, while it was because it uses the NON detrended JMA function – sorry, lost the overview among too many models...

I'm not sure of what happens if you open the chart without having these add-ons, maybe you can still see the output. I've checked other models I'm using, and it appears I'm too affectionate to Jurik. So, either I create a new model for the purpose of this thread, or someone else can post one to be used as a working sample. I'm however very interested on any comments from those who can analyze my sample above.

Marcel

Here's a quick tip for including the data in the chart itself (assuming you have
a recent version of NST).

When you've built you chart, save it, then click on the "Email Chart"
menu item in the File menu in NST. It will ask you if you want to include the data
in the chart or not. Say yes, then it will pop up an attachment in your
email client.

What to do next depends on your email client. If you're not bothered about
checking the chart, then just post it direct to the forum email address.
If you need to see it and your email client will let you, save the chart
attachment (with a different filename). If not, send the message to yourself, then
download the attachment when you receive it.

Hello ?!?

Date :7/22/2005 2:45:13 PM Poster : Marcel

All,

A few quotes to start:

Sunny: "To summarize, I was disappointed to find the lack of response to what I have found to be a very useful indicator. This lack of response has made me a little bit more thick-skinned when it comes to sharing indicators or systems in the forum."

Josh: "This is a long post, so I'll post again when discussion runs to ratios of "evaluation bars" to "Out of sample bars." I have a theory for determining these I'd like to set up for debunking!"

Sunny: "I like your optimism since this is key for this game. I will be interested in following your work in the days ahead."

Josh: "I am interested in sharing."

John: "thank you for leading this initiative. I am hoping this will get me on the right track after many false starts and poor models that perform well with historic data but which are dreadful going forward."

My dear friends – I haven't been in this forum long enough, my apologies if I'm going to be too direct or hurt somebody.

Right from the start I had the sensation that there is good potential on this board, that there are people (frustrated, motivated, beginners, experts etc) out there willing to share and learn. Since for the time being I can dedicate quite some time to it, I'm perfectly fine to do some extra work, kick off initiatives or write a bit more than average.

Mark is doing a sensational job, in this thread he is the driver and he has led us through the jungle so far. I can't find the right words, but he has my fullest support and admiration, because he is willing to share his knowledge and experience, generously, without fear of "giving away secrets", something that could give others the advantage. And he is very smart too, he does not give away cookies, he explains how to bake them, which is also more interesting and rewarding for him.

Now honestly, apart from two other contributors (many thanks to you too!), the rest is zero, only ephemeral appearances. I'm not here to point finger or teach values, but we have to understand that any discussion is effective only if there is CONTRIBUTION. I have the impression that this thread is mainly a dialogue between Mark and me, and lots of spectators around. This cannot be!

Mark has mentioned it a few times, "if there is enough interest, we are going to explore deeper and deeper". No interest (= no contribution), and this thread will die. Is this what we want?

Looking forward for many new articles.
Have a good weekend,
Marcel

Re: What needs to be achieved to build a profitable Neural Net?

Date :7/25/2005 10:58:46 PM Poster : Alan Rhodes

Your post brings up something Ward Systems advocates that I feel very uncomfortable using.

Over simplifying, find a trading system that works out of sample for an instrument, and trade that system until it fails.

My discomfort with this is that selecting successful instruments can be a form of over optimization, in my opinion. I do not completely buy into the personality of stocks theory (that different stocks have different personalities and therefore need different trading systems). True, you know certain stocks are going to be hot, and that a volatility based system will be successful. But all hot stocks cool off, and usually you base your decisions on what is cooled off by other factors then just looking at the stocks.

On 7/14/2005 3:37:32 PM Marcel wrote:
All,

1. Preamble:

As commented in the previous thread "Model Sharing", this new discussion is intended for ALL users of NST. Beginners should herewith get a chance to verify whether they correctly learned their first steps, experienced users will be able to steer and move the discussion into more specific areas of interest.

2. The background:

Before describing the process, let me portray what I do in the context of NST:
- I trade mainly stocks and some derivatives (options, warrants)
- I trade mainly on US markets, plus some European issues
- I trade both sides, long and short
- Trading is unfortunately only a hobby, therefore no Intraday

I'm currently working with a universe of instruments that include:
- Dow Jones Industrial stocks
- S&P 100 stocks
- Nasdaq 100 stocks
- Euro Stoxx 50 stocks
- SMI stocks
- Some selected currency pairs
- A few commodity and Treasury Notes
In total I've roughly 500 underlying instruments, for which I update daily the End of Day prices.

3. The development process:

a) Idea generation

The motivator can be an article describing a new concept to me, or an older model that I browse through (e.g. one of the examples provided on the CD), or a new indicator I discovered recently, or a colleague that asks me for a specific predictive analysis. But most of the times it's the fact that the current model(s) is not performing the way I expect or does not generate (anymore) the wished signals.

b) Draft creation

I rarely start completely from scratch, I usually take as a template one of the models I have at hand and try to adapt it to the new idea. At this point in time, I use a set of maybe 10 instruments whose charts I know by heart. If I'm trying out a new indicator, I'd simply try to analyze it's efficacy with regards to being an input signal.

My latest models all share the same principle, an enhanced versions of one of the examples provided on the CD (I think it's Example 6). I have 3 NNs that independently deliver signals to a trading strategy, which ultimately decides and produces the short/long signals. No model has the same set of NNs. In one model the 3 NNs take input from different categories of indicators, while in another the 3 NNs use the same indicators, but set in such way that they consider different timings (short/medium/long term). By default I make little usage of optimization, limit the amount of EoD data to 4-5 years and usually define 1 or 2 walk-forward test periods of 6 months.

This stage requires a lot of trial & error: I experiment with those wizard parameters I'm most familiar with, then copy/paste the most relevant statistical results into an excel sheet, try the next parameter, copy/paste, etc. After a while I get a picture of which parameters provide the best results for the sample. I create variations of the models and retain those that look to be the most promising.

c) Model testing

Once I have created what I think is the best set of model variations, I test them with the full set of 500 instruments I've in the database. Depending on the degree of optimization, this can take quite some time, but I tend to discard those model variations that take more than a night to complete – simply not practical.

With regards to the data, I keep a set of EoD data for all instruments frozen for a particular date, usually the weekend before I start the development. The development of a new model may take a few weeks to complete and I want my reference data to be consistent over this period of time.

d) Selection and verification

I will then do a lot of manual copy/paste, recording in an excel sheet the results of those instruments that fulfill the following criteria:
- Out of Sample statistics:
- more than 70% successful trades
- double performance than buy & hold strategy
- yearly performance of at least 30%
- Visual check of Out of Sample chart:
- buy/sell signals placed at the right turning points
- no major mistrades or periods of inactivity in the chart
- no major drawdown

If the above 6 criteria are fulfilled, then the model variation with this particular instrument qualify for what I call "tradable list". In average, I'd be able to produce maybe 5-10 instruments for a particular model variation. If the same instrument is present in more than one model variation, I'd keep only the one that I deem the best.

Note: I'm not completely satisfied with my Selection/verification stage. In a recent thread "Empiric Selection Criteria", I've tried to address some concerns and ask a few questions. I'm currently testing the good hints I got there, but I'm also very interested in other's opinions.

e) Implementation

I don't wait long before starting to trade – I don't have the patience to go through another paper trading phase! I'd start to trade a subset of the new model's instruments right from day one, first by "fooling" the system and buying those instruments which were filled in the past and are negative [that's not a joke, I did it!]. For the others, I'd wait and as and when new signals are produced, I'd go long/short accordingly.

Other considerations relative to Money Management are out of scope here and may be addressed in another thread.

4. The trading process

The daily process is very simple and takes only 15 min: In the morning I update the database with the latest EoD data, and I then open all the models and check for new signals. Trades are placed accordingly with the various brokers.

5. A demonstration model

I'm enclosing one of the models I've produced about 2 month ago, that for the sake of this forum I will call "ForumSample001". [I hope that the WebMaster can create the link for the download here.] The file referenced may be downloaded using the following link:

ForumSample001.zip

The model was trained with data up to 31.5.2005 and produces somehow usable signals. It's not the best I have in my arsenal, but it's one of those that do not need any specific add-ons or licensed indicators. If we share models, I think it's important that we select those that can be used by most users – i.e. no intraday, no add-ons.

It qualified for 6 stocks as well as the US 10Y Treasury Yield. Although I follow them with my watch list, I haven't yet traded them.

Best regards,
Marcel

>instrument, and trade that system until it fails.

This was an item I was planning on discussing in detail later in the Curve fitting sections, but here's a quick view of it in the meantime.

Curve fitting is generally bad news. If you build a model and then run through 100 stocks
trying to the find ones that work, or run through 100 indicators, or genetically
optimize (i.e. run through 100's of parameters picking the best ones that work),
then they are all forms of curve fitting.

Here's an example to illustrate the issue. If I was to toss a coin 100 different coins
then each one would either land up heads or tails. And roughly 50% would be heads
and 50% would be tails. Now, I want to build my perfect coin tosing system, so I take
out all the coins that are heads, and I now know that I have a perfect trading system
that will always produce heads. I then start using it out of sample, and it doesn't work.

That's one example. Now, lets do the same thing again. Except, this time, I'm going
to make sure it works, by building an out of sample test too. After I've chosen my
coins that always produce heads, I then create an out of sample test, where I again
select all the coins that produce heads. So now, roughly 25% of my
coins are "heads" producers, and I've proved it with an out of sample test too.

The above are examples of curve fitting by selection and rendering your
out of sample to be in sample.

Essentially any process where you're selecting something to find the best
things that work is curve fitting (in this context), and that is when the alarm
bells should ring. The point is that in any population of results, some will do well
, and some will do poorly just by chance alone. If you then select just the good
ones, then you've chosen something that could have been (and likely was)
goverened by chance.

So that's the bad news. Now for the good news, how do we successfully
use curve fitting.

1. Design a good model first. By designing a good model to start off with, you don't
need to curve fit. (beware about trying 100's of models until you find one that works,
you're just curving fitting again :-)).

2. Curve fit at the end of your design process. I.E. When you have built a working model. By leaving it until the end, you should already have good results, and then the GA is just improving things.

3. Constrain the genetic optimizer. If you're starting with a good model, then the parameters the GA is picking should be constained to reasonable values. (However if you're starting off with a bad model, and trying to find what works, then you shouldn't be using constraints).

4. Calculate the number of Degrees of Freedom in your model (DOF) - aka variables, and validate the model with 30 trades per degree of freedom. This helps you avoid curve fitting, I.E. The more complex your model, the more trades you need to validate it on.

These 4 reasons are why I advocate designing a good model in a process rather than just trying to find one by repeated experimentation.

Now, back to the technique Ward Systems advocate, is it right or wrong? It's right if you use it correctly, and here's why.

Essentially when you've curve fitting, you're trying to fit, well "A Curve". In this case it's a complex function. Now if you can see enough of the function, you can approximate it. The more variables you have the easier it is to aproximate. The less you have, the more difficult. This is why we need to validate it on sufficient trades, i.e. need to make sure we haven't accidentally curve fitted by having too many variables.

Now lets look at it slightly differently. You can approximate a curve with lines. The smaller the lines, the better the fit you get. As the length of the line approaches zero, you get a perfect fit to the curve out of these little pieces. This is called a piecewise linear approach.

So if you keep the lines small (i.e. by keeping your model simple - DOF small), then you can curve fit by retraining the GA/neural nets often using the piecewise linear approach.

Mark,

Thanks for your elucidation on "curve fitting", from this perspective certain observations become certainties and feelings become facts (relativity – Einstein).

Can we concentrate for a little while on:
"1. Design a good model first. By designing a good model to start off with, you don't need to curve fit. (beware about trying 100's of models until you find one that works, you're just curving fitting again :-))."

We have learned from you a few fundaments for building models, like the effects of lag, the principle of TDNNs, learn ability of NNs etc., but how do we mix it together?

In other words we are learning the ingredients (flour, butter, sugar and eggs), but we don't yet know what to do with it.

And are those sufficient to bake something that tastes like cookies?
What other fundaments are needed to "Design a good model first"?

Maybe there are some more aspects that need to be discussed, like:
- Definition of the objective of a NN
- Selection of inputs, what is relevant to achieve the objective
- Indicators classes, what can be expected from them
- Model structures (simple vs. composite structures)
- Where can Trading Strategies play a role
- Etc.

Pardon me for being impatient,
Marcel

>What other fundaments are needed to "Design a good model first"?

Lets stick with the baking analogy for now. So far we've introduced the goal/concept of baking (a model that is profitable). We know that to bake something, we need to build a recipe (a model).

The recipe has an end goal (something good to eat), with 2 possible outcomes, something that tastes good, and something which tastes bad.

So far we've only learnt the basic concept of a recipe. You're still missing the ingredients. After we've gone through the items, hopefully you're going to have a guide to creating recipes, and some of the ingredients (enough to bake cookies), but the type of cookie you decide to bake and the receipe you create will be up to you.

>Maybe there are some more aspects that need to be discussed, like:
>- Definition of the objective of a NN
I would say to pick something that can be predicted. Is it reasonable to predict price? Or would it be better to predict things that produce cleaner signals, like a turning point? From the demo chart for learning, which kinds of things would you say could be predicted?

>- Selection of inputs, what is relevant to achieve the objective
Those are ingredients.

>- Indicators classes, what can be expected from them
Classes of ingredients. I.E. You could say wheat flour would be a class of flour, but you could also use rice flour instead in your cookies.

>- Model structures (simple vs. composite structures)
Personally I prefer simple. The more complex they get, the more difficult they become to build, quantify and test. You can use multiple neural nets (composite structure) to build a model (and many people have been successful doing it), however it does introduce another loose form of creating a better ability to curve fit (because each neural net you add has inputs, and all of those contribute to the degrees of Freedom). So you have to increase your out of samples to account for it. Still, it can and does work.

At some point of complexity though, you reach the issue that you need so much data to test, that in the meantime the function you're trying to fit has changed, or you can't get sufficient data.

>Pardon me for being impatient,
:-)

I need to be sure before continuing that people are comfortable with the concepts so far.
The problem is that with this view of things are built on top of other things, and
the subtleties and requirements for certain technique can be missed.

Personally I always find the best way of learning about something is to experiment with it.

So here are some exercises to post results/charts to this forum (prefably from people
who haven't posted on these subjects yet).

1. Build a 4(entry) 0(exit) lag chart (using real data, not simulated with lead)
and post results.
2. Examples of what inputs and outputs a neural net could learn.
3. An analysis of the amount of noise that can be reasonably rejected by a neural net.

Mark,

> I would say to pick something that can be predicted.
> Is it reasonable to predict price? Or would it be better to
> predict things that produce cleaner signals, like a turning point?

Technically speaking, to predict price as an absolute value seems the worst of the choices to me, first and foremost for the fact that price is not normalized. The output should be a variable that ranges between two limits, fluctuates above or around a fix value (e.g. zero), or is member of a set of values. Better choices would therefore be a probability (0-100%), a change in percent (+/-) or a direction (up, neutral, down).

In terms of strategy, I think the biggest distinction to be made is between "trend-following" and "counter-trend". Most of the time (around 70%) prices trade in a sideways or "range-bound" pattern. By contrast, markets are only in a "trending" mode for the remaining 30% of the time. In statistical terms, commodity and financial markets display a strong tendency towards mean reversion.

But when prices do trend, those trends are often powerful and sustainable, offering low-risk / high-reward opportunities, such that a single profitable trade will often offset numerous small losses. That's the moves we want to capture with a "trend-following" strategy. On the other hand, a "counter-trend" system will measure the "strength" of a market or instrument with the objective of determining when it becomes either overbought or oversold, taking therefore a contrarian position.

Conventional implementation examples of "trend-following" strategies are based on MA crossovers, while "counter-trend" strategies are for instance conventionally implemented based on Momentum Indicator levels.

> From the demo chart for learning, which kinds of things
> would you say could be predicted?

[I assume you are referring to the S&P500 chart]

Well, the very first thing to consider is the dimension of TIME. While one trader may be placing all his tokens on a – from his perspective – big upmove, an investor may observe this same move as a little correction to the mean, being a large downtrend, he will remain short.

In a monthly S&P500 chart, we would therefore observe an established uptrend during the 90's, a correction starting Sept.2000 and lasting roughly 2 years, then the resume of the previous trend.

But since we are working with daily charts, we want to capture those smaller moves that are influenced and at the same time independent from the (monthly) superposed trend. In practical terms, we are prepared to place up to a few trades per month for a particular instrument.

We would ideally be looking for those valleys and peaks, which appear to occur with a frequency of 10-30 bars (days) and that form turning points...

So, are we going to design a "trend-following" or a "counter-trend" system? We get obviously tempted to catch that particular trend-reversal with our "counter-trend" strategy, let the position run by listening to the "trend-following" system, and change direction exactly when the "counter-trend" alarm bell rings!

(Sorry Mark, I'm on purpose not applying what previously discussed with pre-determined exits and 0 lags, only describing the most logical reasoning for solving this problem!)

Can someone else take over now and either correct the reasoning or continue with design considerations?

Best Regards,
Marcel

That is a pretty key statement that Alan has made, i.e. "All hot stocks cool off"
Conventionally, stocks go through modes of being in vogue and out of vogue, and
that breaks models. I.E. A model that has been built for something in vogue, doesn't
normally work on something out of vogue and vice versa. It is a major frustration
for us and breaks models quicker than you can blink.

So the question becomes, are we using the correct model, or is our thinking suspect?

It's common knowledge that the beginning of the trading day and end has high volume,
and the bit inbetween is generally lack luster volume. However, most models don't
consider this issue. Sometimes you'll see people suggest, "I've built the model just to trade between 9:30 and 10am", but it makes you wonder why can't the middle of the
day be traded too, i.e. what process is in play that means it only works at certain times.

The issue at play here is "Time". If there are no trades/demand, price doesn't
change, if there are a lot of trades/demand, price changes. Yet, we routinely change
this rate to a constant time base "Clock Time", and then try to analyze it with fixed
static techniques i.e. why would an SMA of 21 periods be of any use when the rate
of trading is constantly changing?

There are a couple of ways of solving this issue, one is adapting your indicators,
the other is adapting your time base to a new one, lets call it "Market Time".

However this is step 4, and we have 2 and 3 to get out of the way first.

So in preparation for 4, I ask you to pull up some intraday charts with volume, and
look at the patterns in price at different times of the day and see how they
would change if you stretched time in areas of high volume and compressed it in
areas of low volume. I encourage people to post their findings, and then we can
discuss some ways to achieve that process. (If you don't have NST Pro, then
the same exercise can be done with daily bars).

I sent in a chart to not allow this discussion to die, but it shows is what you have already stated, that volume drops off mid day.

I assume you are suggesting that we somehow vary the x-scale in the chart by taking the raw data, pre-processing it and then feeding back into NeuroShell. Be a little patient since so far crude attempts have bombed, but not giving up.

Re: What needs to be achieved to build a profitable Neural Net?

Date :7/26/2005 3:30:18 PM Poster : Marcel

Alan,

I was working intensively with NNs and trading strategies beginning/mid 90's, but gave eventually up because of immature technology (my perspective). At that time, 90% of my efforts were devoted in building the necessary tools, which means developing the NNs, the feeds, the GUIs, reports etc. Little to no time was left to focus on models, especially when learning processes were taking >12 hours to complete.

10 years later I'm taking a second chance – I hope I can learn to drive without having to build the car, this time. I only (re-)started 3 month ago, and although I may not be considered an early beginner anymore, I still have lots to learn. I have gone through several "experiments", all of which were based on the few methodologies documented in the context of NST. Neither satisfied with the approach nor happy with my results, I've tried to facilitate a few discussions on this forum, seeking for answers.

My introduction above is not meant to state the "perfect process", it's simply to document the way I, and probably many other users of NST, are (soon were) developing systems with NST. And it's also to kick off the discussions on the matter.

But I'm grateful for your candid comment – it confirms my observations and fears. So let's push this project further on!

Regards, Marcel

On 7/25/2005 10:58:46 PM Alan Rhodes wrote:
Your post brings up something Ward Systems advocates that I feel very uncomfortable using.

Over simplifying, find a trading system that works out of sample for an instrument, and trade that system until it fails.

My discomfort with this is that selecting successful instruments can be a form of over optimization, in my opinion. I do not completely buy into the personality of stocks theory (that different stocks have different personalities and therefore need different trading systems). True, you know certain stocks are going to be hot, and that a volatility based system will be successful. But all hot stocks cool off, and usually you base your decisions on what is cooled off by other factors then just looking at the stocks.

A dynamic volatility-trailing stop

Date :7/15/2005 7:35:34 AM Poster : reyden

The current trailing-stops are either price or percentage based, in other words fixed. I'm interested trailing-stop, related in a percentage, but the percentage is a function of the stocks volatility over the last 90 days, in other words the trailing stop dynamically changes over time. Any tips will be appreciated.

Thanks

Re: A dynamic volatility-trailing stop

Date :7/17/2005 12:45:29 PM Poster : Matt Jarvis

You really aren't limited to the canned trailing stops that NSTP provides. You can create your own price level. Your first step should be to determine how you want to measure the volatility and compute the percentage function. My thought would be to use the standard deviation of the price or momentum ?

Matt

You may want to take a look at Kirshenbaum Bands and see if you can use them. Admittedly they are not the perfect solution for what you want to do, but they may come close enough so that you can adapt them without custom programming. You can download them for free at the Bowfort Technologies web site

Cybernetic Analisys Add-on - Does it meet expectations?

Date :7/20/2005 5:19:03 PM Poster : Toni

I am considering purchasing the Cybernetic Add-on. I've ordered the book hoping that it will give me a good indication on whether the Add-on will meet my requirements - but the book is still in transit (Post)..... so the question really is whether someone has used this add-on and found it to meet trading expectations? What is your experience with it?

Re: Cybernetic Analisys Add-on - Does it meet expectations?

Date :7/22/2005 4:41:40 PM Poster : Maxwell Craven

I have the add-on and have found it very good. Of course, not all indicator sets have worked for me, and I haven't tried all of them, but the following have been financially beneficial so far:

Cyber cycle and trigger
Itrend and trigger
Stochastic RSI & RVI
relative vigor

On 7/20/2005 5:19:03 PM Toni wrote:

What neural networks can learn, and what they can't learn

Date :7/22/2005 1:14:51 PM Poster : Mark Simpson

Onto the next phase:

Firstly for purposes of these examples, I've created a Sine Wave Indicator. This
essentially just displays a sine wave, but here's the breakdown on the indicator
so you can see how it's created. For ease of use, I've created it as a template file
you can install into Neuroshell.

To create the sine wave indicator, first of all, we take:

CumSum(Constant value(1),0)

This creates a ramp which increases by 1 for each additional bar. It changes
by 360 over 360 bars.

We then need to allow the ability to change the length of the sine wave, to do this
we take the CumSum expression above and multiply by 360/periods, where periods is
the length of one cycle of the sine wave, giving:

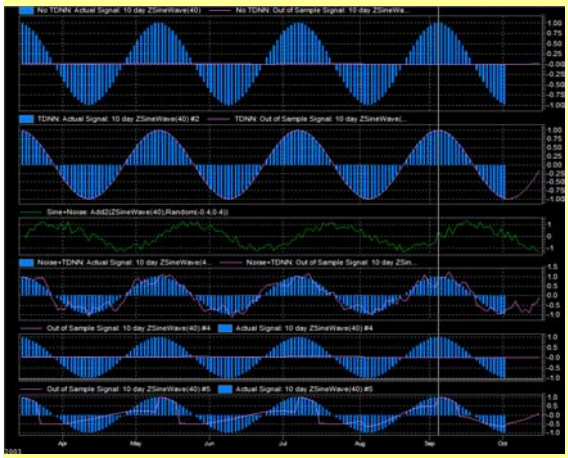
Mul2(CumSum(Constant value(1),0), Divide(360,periods))

This creates a scaled ramp function.

Then we take the Sine of it and we have a sine waveform:

Sin(degrees)(Mul2(CumSum(Constant value(1),0),Divide(360,periods)))

I've saved this as a template file that you can install into Neuroshell, and takes one parameter (periods). The indicator is called ZSineWave and can be found in the
Bowfort Category in NST after you've installed it and restarted NST.



Learning.zip

To see this example, download the above and put ZSineWave.tpl in your Template
folder in your Neuroshell folder (or Neuroshell Trader 4, or whatever else you've named it). The chart goes in the Charts folder.

The example demonstrates how a neural network
learns effectively (or doesn't), depending on the quality and techiques used to feed it.

The first subchart demonstrates a neural network predicting a 40 period sine 10
days in advance. It's input is just a 40 period sine wave. As you can
see the prediction (the magenta line) is terrible. Correlation is -0.0203.
Why is it so bad? Lack of context.

The 2nd subchart adds that context. It's the same chart as the first, but just implements a TDNN this time. This time we get a correlation of 1. The neural
net is perfectly predicting. (as an exercise you can try removing the lags, so you
only have the ZSineWave, and just one Lag(ZSineWave,1)).

The 3rd subchart show's random noise ranging upto 40% of the sinewave being added
to the sine wave. I.E. We're deliberately degrading the ZSineWave with random noise.
This is used in the 4th subchart and is here for reference purposes.

The 4th subchart is the same as the 2nd subchart (i.e. with TDNN), however, the
sine wave is not clean, we've added noise to see how well the net can deal with
this issue. However we're still trying to predict that perfect sine wave 10 days in
advance. Correlation is still good at 0.935, i.e. the net has managed to deal
with most of the noise. However there is some degredation. Try experimenting
with the quantity of noise and see the effect on the quality of the neural net output.

The 5th subchart puts a Cumulative Sum into the neural net as input, instead of
a sine wave. However it still is trying to predict the sine wave 10 periods ahead.
As you can see, the net does poorly on this example. Correlation is 0.0656.
Why? Didn't we say earlier that a neural net can reproduce a function, so why should
it need sine as input, can't it figure it out itself.

The answer is it can, however, we've done something wrong. It's all about seeing similar data in realtime as it does during learning. Cumulative sum is monotonically increasing, i.e. the neural net will never see the same (or similar value) again on it's input,
so it never learns.

The 6th subchart fixes subchart 5, very simply. We take the same cumulative sum,
divide it by 40 and use the remainder of this calculation as input. I.E. We've changed
the input to be a re-occuring ramp of 40 periods instead of just a continuously increasing
ramp. I.E. The net sees data that it's seen before, so it can learn. Correlation
is 0.726, not perfect, but it's obviously learning the function. I leave it as an exercise
to see how you can improve that correlation.

The above serves as a simple experimentation platform on what neural networks can/can't learn.

Incidently, if your fingers are aching from building TDNN's, a quick tip for inputing,
is when you create the "Lag" indicator, where it has periods, put in 1,2,3,4,5
instead of say "1" and it will create 5 indicators. This is a shortcut in NST which enables you to create mutilple indicators with different parameters, and it saves you having to do the same thing 5 times.

In Summary, to predict effectively:

1. You need to have minimal noise.
2. You need to have something that can be predicted.
3. A neural network needs context. If you're not providing it with your indicators,
then you need to provide it using another method.
4. You need to provide data that it has seen before (or similar) for it to learn.

Missing CustomInd.dll

Date :7/24/2005 6:18:06 AM Poster : Marcel

Mark

After installing the 2 files as indicated, I get the following msg while opening the chart: "NST was unable to find CustomInd.dll. Pls contact he solution provider..."
This looks to be the dll that contains the SineWave function, since no Sine actual signal is displayed on the chart...

Where can we download it from?

Tks & Rgds, Marcel

Re: Missing CustomInd.dll

Date :7/25/2005 2:08:15 AM Poster : Mark Simpson

Hi Marcel,

There's isn't a missing dll that's needed. I've also checked the chart to make sure
there isn't anything I've accidentally left in there, and I couldn't find anything.

The ZSineWave function is constructed from the standard indicators
available in neuroshell (CustomInd.dll).

However, if you somehow managed to delete customInd.dll, or some of the indicators
in it, or had an older version of NST which didn't have those indicators in, then the
ZSineWave might refuse to work.

Please check you have the indicators it was built out of in your list of indicators in
NST, i.e.:

Sin(degrees)
Mul2
CumSum
Constant value
Divide

Failing that, what version of NST are you using? Also, is it Neuroshell Trader, or
Neuroshell Trader Pro?

Can anbody else confirm success or not opening the chart? In which case, is it Trader or Pro, and what's the version?

Thanks

Re: Missing CustomInd.dll

Date :7/25/2005 12:07:45 PM Poster : Mark Simpson

Thanks.

I've replaced all the "Constant Value"s with Add2(0,1) and rebuilt the chart.

If you don't have Advanced Indicators Set 1, please delete the ZSineWave.tpl
file in the Template folder, and then save this chart over the old one in the Charts
folder. When you open it, it should tell you that it's recreated ZSineWave and
everything should work for you.

Re: What neural networks can learn, and what they can't learn

Date :7/27/2005 1:26:45 PM Poster : Marcel

Mark,

I finally had some time to go through your instructive example.

Here my comments:

> (2nd subchart) As an exercise you can try removing
> the lags,so you only have the ZSineWave, and just
> one Lag(ZSineWave,1)

Well, for those who haven't tried (it only takes 1 minute), it's interesting to see that by removing one lag after another, the correlation remains always at 1. In other words, one single lagged input is sufficient to perfectly predict.

Now the interesting part:

a) It doesn't matter if you lag this second (delayed) input by 1, 2 or 5 bars, the correlation remains always at 1.

b) A lag of 0 bars obviously won't work, since both inputs provide the same value.
-> Lag(x,0) = x

c) But what with a lag of 40? Easy, you may say, it won't work neither since the second input delayed by the Sine period will provide the same value as the first input.
-> Lag(x,period*N) = x
But surprise, surprise! You try and you will see that the correlation is still 1... Why?

d) By displaying the values we find that:
ZSinWave(40) = -0.15607
Lag(ZSinWave(40),0) = -0.15607 (same)
Lag(ZSinWave(40),40) = -0.1560753 (slightly higher)
Lag(ZSinWave(40),80) = -0.1560805 (more higher)
Alright, a calculation error of the ZSinWave function (a typedef or rounding issue I guess). The curious deduction is that thanks to the little rounding discrepancy between the 2 inputs, the NN becomes capable of perfectly predict!!

> (4th subchart) Try experimenting with the quantity of
> noise and see the effect on the quality of the neural net output

Here some results:

a) Varying the noise level

Graph20050728a.JPG

As shown by the above graph, the predictability of the NN drastically decreases as more and more noise is added to the Sine. Note that values of noise >100% make little sense, the NN is starting to predict noise.

b) Varying the number of inputs

Graph20050728b.JPG

As expected, the more inputs, the better the predictability (correlation). To achieve values of Corr(i) > 0.8, we need a minimum of 5 inputs (current + 4 delayed) – unfortunately at the expense of more DoF. The above figures apply for a noise level of 40%.

> (6th subchart) I leave it as an exercise to
> see how you can improve that correlation.

By analogy to the previous examples, I started to add additional lagged inputs. It can be observed that the NN starts to perfectly predict parts of the wave (to be precise the beginning of the period), while the rest remains still unmatched. This makes sense, since the NN gets inputs (current plus N lagged values) for this particular sector of the wave. So we add more and more lagged inputs...

We don't need 40 inputs (period of 40) to get a Corr(i) of 1, for example current value plus a sequence of 22 lagged inputs is sufficient. But we know that such a high number of inputs is negative in terms of DoFs, we get therefore tempted to delete a few of them. The sequence (0; 5; 10; 15; 20) provides a respectable Corr(i) of 0.979, which is really good already. But we are cheating a bit (Mark will say curve fitting), since we are knowledgeable about the period being 40 bars – what if the period is only 15, then 60, then variable???

I'm curious to know how others did this...

Now to the usual few questions:

> 1. You need to have minimal noise.
Am I correct that we will discuss this under "filters"?

> 3. A neural network needs context. If you're
> not providing it with your indicators, then you
> need to provide it using another method.
What do you mean by "another method" -- in practical terms?

Best regards,
Marcel

Re: What neural networks can learn, and what they can't learn

>Now the interesting part:

>a) It doesn't matter if you lag this second (delayed) input by 1, 2
>or 5 bars, the correlation remains always at 1.
Correct. Sine is a pretty easy function for a neural net to handle so, 2 inputs are
not a problem. More complicated functions can require more inputs to model
with a TDNN

>b) A lag of 0 bars obviously won't work, since both inputs provide the same value.
>-> Lag(x,0) = x

>d) By displaying the values we find that:
>ZSinWave(40) = -0.15607

>Lag(ZSinWave(40),40) = -0.1560753 (slightly higher)
>Lag(ZSinWave(40),80) = -0.1560805 (more higher)
>Alright, a calculation error of the ZSinWave function (a typedef or rounding issue
>I guess).
>The curious deduction is that thanks to the little rounding discrepancy between
> the 2 inputs,
>the NN becomes capable of perfectly predict!!

Essentially a neuron with one input only has one weight in it's
construction, so is limited in the functions it can represent (but
that can also depend on the network behind it). A neuron with 2 inputs, has 2 weights, so it can represent more complex functions.

Now if ZSineWave(40) = Lag(ZSineWave(40),40), which it should do, then
both inputs are the same, therefore both weights in the neurons should be
adjusted to the same value, so it can't approximate the complex function.

So theroectially if you use ZSineWave(40) and Lag(ZSineWave(40),40) as
inputs you should get the same correlation as using ZSineWave(40).

However, they're not equal, they're very slightly different. I think the reason for this
is a rounding issue in sine calculation. E.G.:

Sine(89) = 0.9998477
Sine(449) = 0.9998476

449 is 360 degrees + 89 degrees. So the result should be the same.

However in programming languages, sine can be constructed using a few techniques,
and it might be an artifact of the technique used for sine of the lanaguage NST's indicators are written in.

That's my guess.

>> (4th subchart) Try experimenting with the quantity of
>> noise and see the effect on the quality of the neural net output

Nice work. And you hit it spot on. If you give an NN noise, it will learn
to predict noise (and of course if it's truely random noise, then
you won't get far).

>b) Varying the number of inputs

>Graph20050728b.JPG

>As expected, the more inputs, the better the predictability
>(correlation). To achieve values of Corr(i) > 0.8, we need

Again, superb work. You can see from the graph that at a certain level,
the extra DOF aren't worth the smaller improvements in correlation.

> (6th subchart) I leave it as an exercise to
> see how you can improve that correlation.

>By analogy to the previous examples, I started to add additional lagged inputs. It
>can be observed that the NN starts to perfectly predict parts of the wave

>unmatched. This makes sense, since the NN gets inputs (current plus N
>lagged values)
>for this particular sector of the wave. So we add more and more lagged inputs...
This is because the neural network has to learn a function that is varying.
Essentially sometimes the values are close together, sometimes they're far apart.
You'll often notice that far apart conveys more information to a net.
Or another way of thinking about it is correlation of inputs. If 2 inputs are highly
correlated, then you really only have 1 input. So really the net is just working
off 1 input, and we know from above that 1 input doesn't work in this context.

So when you have inputs 0.1, 0.5 it'll predict well. And when you have inputs 0.997, 1.0
it'll predict poorly.

>We don't need 40 inputs (period of 40) to get a Corr(i) of 1, for example current
>value plus a sequence of 22 lagged inputs is sufficient. But we know that such a high
>number of inputs is negative in terms of DoFs, we get therefore tempted to delete a
>few of them.
22 lagged inputs covers half a cycle of the wave. Half a cycle gives the neural net enough to
learn successfully, because half the cycle can be mirror'd to produce the other half.

>The sequence (0; 5; 10; 15; 20) provides a respectable Corr(i) of 0.979,
>which is really good already.
Correct. This is because all 5 inputs have different values (are uncorrelated). And they
always will be uncorrelated.

>But we are cheating a bit (Mark will say curve fitting),
I wouldn't call that cheating personally. You know your data and that's good. Provided the
relationship is there in time, i.e. data 20 periods ago has a relationship to now (which it
does for the sine wave), then that's fine to do that.

>since we are knowledgeable about the period being 40 bars – what if the period is only 15,
>then 60, then variable???
Try it out. What I believe you'll find is that provided your cycle length isn't too long
and isn't too short, i.e. you're getting different enough samples and good coverage,
it will work for many different periods.

As far as variable periods (I'm assuming you mean varying through time). That would be
interesting. Essentially the neural net could have a hard time learning. But
you could always build an indicator to measure the length of the cycle and feed that in
as one of the inputs.

>I'm curious to know how others did this...
Me too.

>Now to the usual few questions:

> 1. You need to have minimal noise.
>Am I correct that we will discuss this under "filters"?
Yes. Essentially a filter removes noise and gets to the underlying
signal. However, the catch is it adds lag, and we don't want that either.
But we'll get into all of that in filters.

> 3. A neural network needs context. If you're
> not providing it with your indicators, then you
> need to provide it using another method.
>What do you mean by "another method" -- in practical terms?

Say you had RSI, and you wanted to detect a peak in RSI, you'd need 3 inputs
to the net i.e.:

RSI
Lag(RSI,1)
Lag(RSI,2)

then you could train a net to recognise peaks. That's context with a TDNN.

Now for the other method, we could provide context in an indicator itself, i.e.

And2(Lag(RSI,1)>Lag(RSI,2), Lag(RSI,1)>RSI)

This indicator would output a 1 when RSI peaked. Then you would feed this indicator as 1 input to the neural. I.E. The indicator has context. Another example would be the candelstick patterns in NST.

Thats great work Marcel. You have a knack for testing things out, and analysing them completely.

Re: What neural networks can learn, and what they can't learn

Date :8/3/2005 11:29:19 AM Poster : Marcel

All,

This is for the records and to close off this thread:

>> since we are knowledgeable about the period being 40 bars
>> – what if the period is only 15, then 60, then variable???
> Try it out. What I believe you'll find is that provided your cycle
> length isn't too long and isn't too short, i.e. you're getting different
> enough samples and good coverage, it will work for many different
> periods.

a) Period of 15 bars

I was personally surprised with this one! Using subchart 6 which has 1 single input Remainder(CumSum(Add2(0;1);0);15), the NN performs almost to perfection with a Correlation(r) of 0.998 – no need to add lagged inputs.

I got the impression that the time series is apparently simple enough to be learned "by heart" (= by value). This led me to the assumption that more hidden neurons would help the NN to learn "by heart" also a period of 40 bars. False, changing the wizard parameter has absolutely no effect. Any better interpretation?

b) Period of 60 bars

Not much to add here, 60 bars are simply a bit tougher to learn, but good results can be achieved with 1 current + 4 lagged inputs (E.g. sequence (0;3;7;17;29) produces corr(r) of 0.969).

c) Variable Sine Wave

LearningTake2 (data saved).zip

For this simulation, I've created 3 time series:
- SinAM: An Amplitude-Modulated sine wave
- SinPM: A Phase-Modulated sine wave
- SinAPM: A sin wave modulated in both, Amplitude and Phase

c1) The 1st prediction

Subchart 2 implements a TDNN with 1 current + 9 lagged input (sequence 1;2;3;5;7;11;13;17;23) – in my opinion pretty costly in terms of DoFs, but it's only for the purpose of this example.

- SinAM: Can easily be perfectly predicted (Corr(r) of 1.000) also with much less inputs. It seems that changes in amplitude do not present a big challenge for the NN.

- SinPM: In this example we achieve a Corr(r) of 0.731. Changes in Phase appear to be a much tougher task for the NN. This can be linked to a discussion we briefly touched earlier on (http://www.ward.net/cgi-bin/Forum/Forum_Article.asp?a=2568) regarding time compression, that's essentially what happens at higher frequency. I haven't yet used any adaptive techniques, I guess we will introduce them when discussing indicator classes.

- SinAPM: With a Corr(r) of 0.801 somewhere between the other two. While the predicted signal seems to follow well low frequency phases (slightly lagged one may observe), it gets out of synch when abruptly moving between extremes at high frequency.

c2) The 2nd prediction

Subchart 3 is simply to introduce the first derivative as an input. With only 2 inputs we achieve remarkable Corr(r) levels of 0.986, 0.675 and 0.684 respectively.

Feel free to find more efficient ways to feed the NN – hopefully you post the results in this forum...

Best Regards,
Marcel

If 15 integers, i.e. 0,1,2,3,4,5,6,7,8,9,10,11,12,13,14 can be memorized
by the NN to provide an output of 15 sine values. Then, to memorize a 40
period sine wave, you'd need 40 integers. (I believe), i.e. 15 integers to memorize
a 40 period sine wave wouldn't work.

>- SinAM: Can easily be perfectly predicted (Corr(r) of 1.000) also with much
> less inputs. It seems that changes in amplitude do not present a big challenge
> for the NN.
Correct. This is because really it's just a function of 2 sine waves. As a NN learns
functions, it's unaware of what goes into a function, therefore a complex function
invariably is no more difficult to learn that a simple one. I.E. It's function
imitating machine.

>- SinPM: In this example we achieve a Corr(r) of 0.731. Changes in Phase

>when discussing indicator classes.
Yes, adaptive indicators are one answer to this. Infact what you need is some phase
measurement indicator that you would add as one of the inputs, then I would
expect the correlation to be back near 1. Essentially the neural net doesn't have
enough information without it. There are a few ways of getting this one to work
when we get into time normalization. In the meantime some of Ehlers cycle
length indicators would work as that additional input in this case.

>- SinAPM: With a Corr(r) of 0.801 somewhere between the other two.
>While the predicted signal seems to follow well low frequency phases
>(slightly lagged one may observe), it gets out of synch when abruptly
>moving between extremes at high frequency.
Correct, because it's a half way house, you get part of some results and part of others.

Quote.com

Date :7/22/2005 4:18:31 PM Poster : Ward.net Webmaster

Today, 7/22/05, Quote.com ticks have been updating yesterday's bar, 7/21, all day as far as we can tell, for many stocks. Quote.com tech support has been unavailable, so it is unclear if they even know. So please inspect your data carefully today and Monday if you are a Quote.com subscriber.

Re: Quote.com

Date :7/25/2005 9:57:27 AM Poster : Ward.net Webmaster

Update on this issue, Monday July 25, 2005:

As far as we can tell, some Quote.com servers have missing data for daily stocks either on 7/21 or 7/22, probably depending on which server you get on. We managed to get all the data when we got on server cc15a (209.202.236.35). So if you are using daily bars, make sure you have no missing data for 7/21 or 7/22. If you have missing data, try deleting the files from the Server/data folder in the NeuroShell Trader 4 folder when NeuroShell is down, and then bringing NeuroShell back up and reloading data. Tell Quote.com of the problem - if you can't get them, it isn't you - we can't get them either.

The paradox

Date :7/25/2005 7:50:23 PM Poster : Alan Rhodes

I will start with the assumption that the one common trait of the "New Market Wizards" is that they were either all doing something that nobody else had ever done before, or doing it differently (my interpretation).

I plan on periodically reviewing the posts and capturing what is said in a summary document. That way we have one central document that contains all thoughts as we approach the mindset needed to do things differently.

It was my discussions with Marc Simpson that got me thinking about things differently, and he already shared what he told me.

The paradox is that the wide open discussions that will ultimately lead to something different that works has the potential to open it up to the world, in which case it will no longer be different.

Side note #1 - If you do not hear from me for a while, it is becuase I am on a forest fire. The next time I go I expect to be gone all August.

Side note #2 - NeuroShell is back to acting normal on my computer.

>in which case it will no longer be different.

That's a very good point, and is why I'm not providing pre-baked cookies (as Marcel says). If I did, the cookie would be soon eaten and there would be no more. By learning how to build our own cookies, everybody ends up with a different cookie. Sure they may have flour, butter, sugar and eggs in, but they're all different.

Also, if you can't bake cookies yourself, then you're always reliant on someone else to bake them for you. In terms of longevity, this is a risky situation to be in, in my opinion.

However, I don't claim to have all the answers either. I've been on this journey for a while, as most of you have, and I've picked up a few things along the way. That's why I encourage other people to share the information they've picked up too.

Alan,

First of all welcome as an active contributor, I'm sure I'm not the only one appreciating it.

I fully subscribe to the summary document. In fact I was planning to draft it last weekend, but I'm more than happy that someone else was quicker than me.

With reference to "baking the cookies", I hope this document can contain the most important recipes to build a successful system. Well, it won't be that simple: Everybody can bake with the help of a recipe, while the document produced herein will only be useful for those who have followed the discussion and its evolution.

For me one of the most important statements made so far from Mark is (http://www.ward.net/cgi-bin/Forum/Forum_Article.asp?a=2540):
"The issue for a lot of people (me included when I started off) was that I didn't truly understand what a neural net was doing. I treated it as a magical black box, which did things that were truly wonderful, but I wasn't sure how :-). Now I regard NN's as being dumb functional estimators that depend on clean data with a relationship being fed to them. Essentially you have to do the leg work first with the inputs/outputs you're providing. If there is a function there, the neural net will find it, and the clever part is that it saves you having to figure out the relationship. But the relationship MUST be there first."

The above very well documents the paradigm shift from experimentalist (when you build systems based on trial and error) to methodist (when you emphasize on and apply systematic procedures).

Is this maybe what you refer with "It was my discussions with Marc Simpson that got me thinking about things differently, and he already shared what he told me."?

Regards, Marcel

Re: The paradox
Date :7/28/2005 2:27:13 PM Poster : Alan RHodes

Actually Marc made me run through the S&P experiment which taught me two things. First, the magic number 4. That reminded me about the 4 period lag in the Hilbert transform, and I realized that 4 is a relatively fixed number. Until then I assumed lag varied.

The second thing was the importance of context. I plugged a moving average into the S&P experiment: (MA, Lead(MA),1 Lead(MA),2 etc. I found it totally not predictive of anything, no matter how much lead I gave. I needed a MACD to work. That taught me the importance of context and got me thinking about that more.

Most important, he caught me at a time when I realized my project plan based on the yellow brick road was not going to work. I started to wonder if it was possible to do things differently, and he convinced me that it was possible.

One of my jobs has been and starting again is a project manager. Since in the systems design business we are sometimes doing things that have never been done before, often times there is a "figuring out what we need to know" phase, "figuring out how to do what we need to do" phase, and a "doing it" phase.

Ideally what I would like to see is a project plan that evolves over time that ultimately tracks all lessons learned and does ultimately leads to a very profitable trading system. The lessons learned becomes critical as part of the contÐuning quality improvement.

As the document evolves though, it will reach a point where I will not want it posted on a public forum like this.

And I have to confess, besides needing to be organized, I need something like working on a project plan so I do not feel overwhelmed. I was already learning two new software packages at work (Nessus - our security software and SMS - our configuration management software). Yesterday I started learning Microsoft Project. Though relatively easy, I started to feel totally overwhelmed. I was not excited about coming home, tackling studying my friends work, figuring out the experiment Marc posted with the sine wave, and figuring out what Marc is doing with some other work. The way to deal with those feelings is to have somebody to talk to and help organize your thoughts and feeling like a team.

It gets back to what motivates me. I guess I have a dream of retiring, trading six months a year, fighting forest fires 2-3 months a year, and spending the money I earn trading and fighting forest fires the other 3 months. Also I love talking about this stuff and experimenting. Flip side, I totally hate reading about the math. My daughter was tested for reading disabilities and the person said it was obvious from my speech patterns that she inherited it from me. But what makes awful at reading math makes me good at things as meeting facilitation. And I have been often told I am a great math teacher. And when I got my BS in computer science, everybody wanted me as a study partner since I helped organize their thoughts from what they read in the book.

I am home on a/l waiting for bark dust to be delivered, and I need to figure out why they are late. Catch you later.

>is a relatively fixed number. Until then I assumed lag varied.
It does vary. 4 is about the lowest you can get away with an amount of
minimum amount of smoothing that can produce money (taking into account
normal trading factors). I tend to focus on this
value because I want minimum lag but enough of a signal to be useful.

I.E. If you're smoothing 2 periods, then you have 1 bar (approx of lag), but the
signal is so active that it's no use.

If you say took an SMA of 100 periods, then the lag would be very appreciable.

A good ball park is that with conventional indicators, lag varies from 0.5 - 0.25
times the length of the indicator.

>The second thing was the importance of context. I plugged a moving average into

>work. That taught me the importance of context and got me thinking about that more.
This is because price is a value that changes, i.e. over time (unless you're learning
on purely sideways motion), then the neural net will see data that is nothing like
what it trained on, therefore learning is tough. As
an SMA is just a smoothing on price, it's the same result.

MACD on the other hand is repeating. I.E. It's centered around zero, and maintains
roughly the same range throughout the data series. So the neural net can learn.

>a. Wavelets -- I have barely touched the surface on this, and I doubt I
>will be able to without custom programming (frequency and amplitude all
>have meaning, and I cannot look at trends without programming). I can
>predict major moves with Wavefin, but I cannot predict which way they will go.
Direction is not an issue, you can always make volatility based trades with
options. I.E. If you buy a call or a put at the same time, then if the move is
large enough, then one becomes worthless and the other one adds value.
Option trades are obviously risky though and it's recommend to take
an options course first if it's new to you.

Incidentally, volatility is inherently easier to predict in general than price. If
you have a system that predicts price correctly 60% of the time, I would say that predicting volatility would be correct 80% of the time from my experimentation.

Attached is a beginning attempt to summarize the thoughts going through my head as I read the posts. Feel free to add to it and make a group thought, not an Alan interpreatation of group thought.

I have not covered the Sine Wave thought exercise yet since I do not have the advanced indicator set, and stupidly beatingmy brain against the wall, had not yet read the solution. Also it was so counter intuitive that initially I had zero ideas as to what was a solution that would not curve fit to a sine wave.

Re: Thread Discussions
Date :7/26/2005 12:40:28 PM Poster : Mark Simpson

Alan,

That's a good summary.

Here's the answer to this one:

>b. Using the concept of setting stop losses at 50% of your gains on a 50%
> profitable systems, what does that mean in real life? In other words, when
> Marc says "yes, profit targets. Pick your entry price and say add "1-2%" to it.",
> how did he develop the figure 1-2 %? And does that mean you set your stop
> losses to (0.5-1%?

1-2% is just an arbitary value to mean picking "Small profits". It's not set in stone, I
just picked that to cover comissions and make a small bit of profit and be an
amount we'd see for most securities (and I err'd on the conservative side).
Some securities won't be able to manage 2% consistantly, and some securities
could be able to manage say 10% consistantly. The target depends on how much volatility there is in what you're trading. Essentially you need to tune it to an amount that is consistantly successful, i.e. avoid being greedy.

Also, it depends on how predictive your entry signal is. If it's good, you can
likely up your targets.

To be successful at this strategy you obviously need low comissions.
Cheap commissions with a good hands on trading interface can be found at http://www.interactivebrokers.com in case you're not getting the best deal with
your broker. Also, for all you international folks, IB allows you to exchange money
at close to interbank rates, for when you're changing into your local currency.

Regarding the stop loss. To me a stop loss is a function of risk. I always would
want a stop loss in case (due to equipment problems or tradable/market/world events),
however if I have a better model, the risk profile will be different than
a poor model and stop losses would be different.

A consistantly good approach would be to have your stop loss at half the value of
your target. With that approach alone, you could consistantly make money with a 50% successful system. However, the model may preclude this from happening.
E.G. If you have a model that consistantly heads down before it heads up, you could
get stopped out every time.

It's very much a personal decision,
and one that NST allows you to simulate with trading strategies. Money management
is a seperate topic (and one I'm not going to get into as there are many
good books written on it), however be aware that with a good model, bad money
management techniques can sink you.

Re: Thread Discussions
Date :7/26/2005 2:57:53 PM Poster : Steve Eberbach

Mark: "E.G. if you had a model that consistently heads down.....you could get stopped out every time."

Conversely, you could achieve negative slippage by using limit orders to reverse your position instead of stop orders! That is what I meant earlier by most often "trying" to trade against your rules instead of just with them, and having multiple sets of conditions for reversing position. How can this be done? In NST I write a trading strategy using different conditions for both limit and stop orders and let the optimizer tell me which way is working best.

While I cannot propose a trading system which works consistently using this idea, I can say that I have learned a lot about price behavior which I would never know if I had not tried it.

Superfical semi-full disclosure

Date :7/28/2005 10:15:02 AM Poster : Alan Rhodes

Since the primary premise of my job is that the best decisions are made when all available information is on the table, I figured I should practice what I preach.

Attached is a superficial snapshot in time of where I am at using NeuroShell to develop trading systems. It is superficial since I need to get the gym. It is only a semi-disclosure since I have a good friend I work with, and I cannot divulge ideas he taught me or less frequently I have developed jointly with him. There are also some ideas which I will be pursueing thanks to some emails from Marc, but I have a funny feeling he will divulge all these thoughts anyway since he alluded to them already, such as normalizing time.

This is no big deal since I think there is not enough information for anybody to develop the killer trading system from my disclosure since I have not been able to do so, so secrecy is not important.

Neural Net search for Functional Dependence

Date :7/28/2005 5:18:02 PM Poster : James Siebert

Greeting fellow data explorers,

I have been exploring Neural nets & data-mining for several years now,
and Neuroshell Trader software for a little over a year.

I have been intrigued by the free exchange of ideas in this forum,
and thought I might have something to contribute.

Neural Nets should be no more a mysterious "Black Box"
than are the results from say a mathematical equation.

From a Math perspective, when you crank input values
into a Function, you should get quite "predicatable" output values
back out, as the result.

Example: given the function

f(x) : x^2 -2x + 1

if you feed it 5 as input you would expect 16 as a result ...
very predictable. no problem.

A problem may arise, however when I tell you I just got a result of 25
can you tell me what the input was?

Yes, you can always solve the equation

25 = x^2 -2x + 1 for x

25 = (x-1) * (x-1)

25 = (x-1)^2

5 = (x-1)

5 + 1 = x (some equations are not so easy to solve)

However, what do you do when you only think (theorize) there is
a predictive function there, but you have no idea what the equation should be?

There's nothing to solve, only a hunch to prove, or disprove.

This is where Neural Nets (NN) can help.
Since NN use math to try to "approximate" the functional relationship
between inputs and output (assuming such a relationship actually exists).
This is especially helpful when "Noise terms" make the hope of finding a nice, neat equation nearly impossible.

NN try to constuct a generalized Formula or Polynominal
that closely estimates of the relationship between inputs and outputs.

NN tell us if there is any merit to our theories. (aka. any correlation)

A trained NN should be able to take a set of unknown Input Values
and make an "very educated guess" about what the Output value should be.

I picture NN as a "function machine" like this

f(x,a,b,c) ==> y

the mission of this NN machine
(really a multi-term polynominal, with various weighted coefficients)

is to keep adjusting an input's importance, until each input is "assigned"
its appropriate "functional role" [its weight] within the "context" of all the other
functional inputs used.

It does this by Minimizing Prediction Errors
and Maximizing Predictive Successes
(thru iterative feedback adjustments based on x:y Correlation r-Scores)

Neural Nets cannot predict anything (accurately)
IF the "theorized functional dependence" between inputs and outputs
is faulty, and does not really exist.

Here's are a couple xls, the illustrate the concept of Correlation predictions in action.

Functional_Dependence_and_Predictions.xls
Functional_Dependence_and_Predictions_3D.xls

Also shows what happens to r-scores when Noise is introduced,
and a possible technique for Noise correction (using previous Lagged Output result, as an input)

Thank all for the many interesting posts,
Hope you find the xls examples helpful.

Data Feeds for Neuroshell Trader Professional

Date :7/29/2005 5:14:21 PM Poster : Buzz

New to the program. Anyone have a favorite data feed they can recommend for the program. Looking for one that has price data as well as other economic or fundamental data on the economy such as daily interest rates. Also not so pricey. Lookinh for EOD data. Any recommendations?

Re: Data Feeds for Neuroshell Trader Professional

Date :7/29/2005 7:23:00 PM Poster : Alan Rhodes

I have used
1. Esignal - I like the forex futures data since it is a full day, not US market hours, making models match the way my eye used to work. Also really like the fact that they have live people helping you.
2. Reuters - I like the fact that it is a true no brainer to use. Lots of indices. Futures data is totally thumbs down. You can cheat by paying for two months of data, setup your computer in ten minutes to download 15-20 years of everything for systems development, wait overnight for it to happen, then close your account.
3. Quote.com - I only used intraday, so no opinion about EOD. They claim full Forex, but it was only market hours data. Lots of indices, possibly the most. Almost went ballistic two years ago when I tracked a trade for two weeks, was about to place it, then had a technical problem where I had no data feed for 5 days. They blamed Metastock and Metastock blamed them, so not sure.
4. CSI - Plus is the fact that they offer everything. Also their multi-market analyzer is super cool. Downside is that it is a bear to use.

The simplest way is to create your custom portfolio in either CSIM or MS format, both Metastock formats which are directly readable by NST without conversion. I have been using CSIM without problems.

There are several ways to do this. I use a txt file. CSV also works, as does Metastock format. I don't remember if CSI format works -- I'm not at home and can't check for several days.

Hope that helps.

This is a complicated issue, because there are so many variables between the data services themselves and each individual's computer, internet connection speed, etc. I found that for my purposes Telechart (http://www.worden.com) was the best overall solution. (Be aware that the Telechart data must be exported to Metastock format before it can be

read by Neuroshell, but this process is easy to set up and can be automated.) I hope this recommendation is of some help.

If you need futures then I'd seriously consider using CSI which also needs converting to Metastock format. It has a lot of useful information for futures. I also use Esignal but am not impressed by the NSDT interface into Esignal as it seems flaky. Its some time since I used Prophet and I believe its improved. That leaves me quote.com which when it works (see the forum for quote.com issues) is ok for stocks but incomplete for futures. Overall I'd like to see a CSI interface to NSDT.

NeuroShell should read CSI EOD data fine, as long as you aren't trying to get it directly out of their Unfair Advantage Database. We are aware of many eSignal problems that you have, but in the US at least, our users do not report them (there are a couple of others in Europe). Lately we have to say eSignal is stable but Quote.com has a number of issues. Prophet now has continuous futures EOD, adjusted and non-adjusted, which may make them more attractive than either Quote.com or eSignal for futures traders.

Thanks for your input everyone.

My research comes up with prophet @ 39.95 per month or 399.00 per year (neuroshell deal) for all their EOD database including futures; which offer continuous contracts and can be adjusted or non adjusted. Sounds like a pretty good deal to me. I used prophet in the past and hope they are operationally ok. I will try and let you know.

Thanks again,
Rich Buzel (BUZZ)

Using NN to test a Hunch about Z-Score

Date :7/30/2005 2:50:31 PM Poster : James Siebert

Hi again

I've always had an interest in Z-Scores,
since I learned about them in Statistics course at college.

Z-Scores have many benefits as a Indicator.

Here are a few:

1) They normalize the data series
2) They introduce no lag to the data
3) They allow "apples to apples" comparisons
4) They "score" today's value within the "context"
of all the values in the Z Lookback Window
(each Z-Score has built-in context)
5) They act like a relatively smooth Oscillator

Well what about my Z-Score "hunch"?

Since Z-Scores measure values in units
of "Standard Deviation" (SD)
and SD's represent a "partitioning"
of the sample group into similar sub-groups,

I've always imagined this as:

Z-Scores between 0 and 1 were "run of the mill"

and
Z-Scores moving from 1 and 2 indicate
"something significant is happening"

and
Z-Scores greater than 3 indicate
"something very unusal is happening"
(within the context of the Z window)

In other words,
"Z-Scores don't stay above 3 for long."
Conversely, there is a tendency for Z values
to return to the Mean Value (Z = 0 SD)

The Z-Score calculation is designed
to "normalize" the sample data, in such a way that
0 is always the "average" value for the sample group.

SO ... my theory is this:

Since the day to day movement of the Z-Score
resembles an Oscillator centered on 0,

When that Oscillator is moving up,
and crosses above some Threshold near 1 SD,
I should pay attention, and probably Buy.

And when that Oscillator starts to correct,
moving back to the center
I should probably Sell.
This Move back should be indicated by
the Z-Score crossing below some Threshold near 2 SD.

SO, I asked myself,
How can I use NeuroShell
to prove or disprove this Z-Score Theory?

If the Theory holds up,
How can I use NeuroShell
to improve upon the predictive results of the Theory?

Attached is a series of simple NeuroShell test charts
to explore this Z-Score Theory.

Results here lead me to believe
that this Z-Score Entry-Exit plan has potential:

ZScore_Theory_Experiment.zip

Zip File includes 5 progressive NeuroShell charts
that illustrate my "test plan" to validate the Theory:

001) Theory_Z1SD-Z2SD 001_A INTC Validated NN 23.cht
002) Theory_Z1SD-Z2SD 002_A INTC Implement TS2 12.cht
003) Theory_Z1SD-Z2SD 003_A INTC Retrain NN 25.cht
004) Theory_Z1SD-Z2SD 004_A INTC Implement2 TS1 34.cht
005) Theory_Z1SD-Z2SD 005_C INTC Optimized TS3 18.cht

The Goal/Result of each Chart:
---

001) Build the Indicators that represent the Theory;

Use a Neural Net Prediction, to see if a profitable
"Solution Space" exits for the Inputs Variable

f(x,a,b) ==> y

f(ZScore Value, Entry Threshold Value, Exit Threshold Value) ==> Profitable Trade

The UNOPTIMIZED NN, using default inputs, got 23% profit

Check. Theory has a solution space. (It has merit)
---

002) Build a Trading System using the "validated" Indicators;

This is the "conduct the Experiment" [Implementation] phase.

My 1st Trading System, using the using default Indicators from 001

performed poorly (-1%)

A visual inspection of TS1 Entry and Exits points
told me the problem was on the Exit-side.

It seems that "failures" were occurring
on those cases where Z-Score Values never reach as high a 2 SD
(the crossbelow(2) Exit trigger never fires in those cases)

SO, in the 2nd TS, I added another Exit condition to deal with this.
(this extra crossbelow(1), in effect acts like a STOP)

Check. TS2 captures the theoretical SD Profit Range
(12% profit, good but not good enough, onward)
---

003) Time to Revisit the NN Validation process,
taking into account the extra Trigger,
called for by Implementation test (002)

This time I let the NN OPTIMIZE to find the
the "best" Input Parameters (per NN approximation).

Re-testing the Modified NN, is still profitable,
and improves upon the original NN (23%), with a 25% profit.

I plug in the New Thresholds found by NN-tuning
into ALL the Original Indicators.

1.0 becomes 0.51 GoLong
2.0 becomes 1.38 ExitLong

Check. Including a 2nd Exit trigger, as a STOP,
improves the profitability "Solution Space" for the NN.
---

004) I conduct the TS "Implemenation Experiment" again.
This time using the NN-tuned Profitable Thresholds,
in also TS conditional triggers.

1.0 becomes 0.51 GoLong
2.0 becomes 1.38 ExitLong

Trading System 1 now gets 34% profit (1 Exit Trigger)
Trading System 2 now gets 16% profit (2 Exit Triggers)
using the NN recommended Entry/Exit Thresholds.

TS2, the one with the "stop" improves from 12 to 16%
But TS1 has improved MUCH more (from -1 to 34%)

It's seems the Adjusted SD thresholds,
are now LOW enough,
that the upper "cross-below" Exit (2-SD)
are NO longer resulting in missed Exits.

The 2nd "stop-gap" exit (002) is no longer needed,
and does not help capture as much the profit (TS2),
once the appropriate SD Thresholds are used by both TS.

SO ### My orignal Z-Score SD Theory appears to hold water;
it's just that my human-estimate of the Range 1 to 2 SD
needed some tweaking, provided by NN search algorithms. ###

Check. Theory looks promising (34% promising)
---

005) Took the profitable TS1 from (004)
and attempted to optimize it further in TS3,
by Parameter Input Optimization,
and various Training objectives.

The best result I could get with extra TS tuning was 18%

No Check. TS1 in chart 004 seems to capture
the Profitable up-legs (INTC) with the most accuracy (34%)

==========

Addendum: additional testing & extensions on Theory

This Z-Score Theory still should be further tested.

1) By starting with TS1 Chart 004, I would
try it with several different Stocks to
see if the NN-tuned SD Threshold values
are "generic" or "specifically-tuned" to Intel Price series.

2) By starting with TS1 Chart 004, I would
try to "mirror" the Entry and Exit conditions
for the Short Trades, as well, and not just Long.

Negative Z-Scores should behave similarly to
Positive Z-Scores, except that Negative Z-Scores,
tell you the Price is moving BELOW the Norm
(with Norm defined as 0 within the context of the Z-window)

==========

as a general rule I using NN for
testing, validating, and tuning Ideas. (rough cut prototypes)

and TS for making those Ideas
interact with the Data Series
in an Objective, True or False matter.
In Trading Systems, I'm looking to construct
Logical rules, Conditions, and Triggers,
that are well-defined, with little ambiguity. (finished consistent application)

I want to be able to Know Why a trade fails
(ie. be able to "measure" the failure points)
Neural Nets make such objective measurements
quite difficult.

"Out of Sample Signals" may accurately "approximate"
the N-Dimensional Solution surface (when it exists)
but at those points where OS Signal predicts incorrectly
you usually have no clue as to Why.
And so little idea what to fix in the NN,
without a lot of "trial and error".

Comments, questions ?
(if you read this far, thanks)

Take care

James S.

(Newbie)

Z-Scores Hunch some Follow-up Tests

Date :7/30/2005 4:10:17 PM Poster : James Siebert

Short Postscript:

I acted on my recommendation (at the end of last email)

> This Z-Score Theory still should be further tested.

> 1) By starting with TS1 Chart 004, I would
> try it with several different Stocks to
> see if the NN-tuned SD Threshold values
> are "generic" or "specifically-tuned" to Intel Price series.

WELL I did just that ...

This Trading System and its NN-tuned Threshold parameters
seem to be "generic" (at least generic for "tech stocks" anyways)

Here are the results from my quick follow-up tests

ZScore_Theory_followup_tests.zip

004_a AMD 32%
004_a MSFT 14%
004_a NVDA 84%
004_a ORCL 14%
004_a SUNW 24%
004_a SYMC 30%

Perhaps I was too quick to post my Z-Score Theory. (LOL)

I threw it together yesterday as an Example exercise.

Did not realize it might be conisistently profitable,
se la vie.

Feel Free to use the Theory,
to improve upon it and to use for trading.
(my contribution to the Forum,
and the "free exchange" of Ideas.)

Let me know what improvements you come up with.

If you strike it big with the Z-Score Cross System,
drop me a Post Card.

later

James S.

==========
Notes: my file naming conventions

number like 004 indicate version number in series

Alpha_Tags: _A, _B, _C, or _D indicate Level of Optimization (none to full)

Number at the end indicates the Annual Percent gain of the System

TS# right before end indicates which Trading System had the Profit

NN# right before end indicates which Neural Net had the Profit
==========

Re: Z-Scores Hunch some Follow-up Tests

Date :7/31/2005 6:46:26 PM Poster : Mark Simpson

Hi James,

You're spot on with Z-Score. Try this out though and see if it performs better,
just go short on a Zscore > X and long on a ZScore <X where X is some value <> +- 2.
You'll find it works pretty much on any security.

I see ZScore as a certain class of at least zero lag (and arguably leading) indicator.
This is a probability class of indicator. Kind of like this:

If you were to say, what is the probability of an event happening? Now take a contrarian
view, and say if Z-Score reached this high a value, what is the likelyhood of it turning around and heading the other way. As more extreme values happen less frequently it's
reasonable to assume that they will revert the more extreme they are.

So it becomes a trade off. I.E. The more sure you want to be that it will revert, the higher the absolute value you look for. But that comes at the expense of trades. I.E.
3 SD events happen less frequently than 2 SD events.

Also, you'll note things like 3SD events will often show up at the same time in many
stocks at once due to a "market". So just saying, I'll scan the market for 3SD events
might not be too useful either if you want to trade frequently.

With the probability type indicators you can achieve 60-80% successful trades
depending on how extreme the level is that you're looking for. You can get even higher
success rates, but then you don't get enough signals to be practical. This is a zero-lag
technique that can be used to remove the 4 bars of lag at entry.

Another probability type indicator is the "Probability of a Turning Point" type of
indicators in the Turning Points add on. And pretty much anything that indicates an
extreme value of something with zero lag, that you can take a contrarian
approach with.

However, say RSI being an extreme value won't work, because it's not zero lag in the
first place.

Also, bear in mind that looking for a peak/valley in Z-Score would add lag for peak/valley
detection.

Another gotch ya is trend. Sometimes a longer term trend with shorter term Z-Score
can end up with the ZScore not producing the required action, and the Z-Score
starts reverting to the mean prematurely, as of course the mean is now following the trend. However, this doesn't happen often enough to cause any major problem
if you don't use excessively short Z-Scores.

Mark

Thanks for the pointers on Z-Score
Very Helpful.
Especially the "gotchas" at the end.

I never thought about Z-Score being
"eclisped" by a longer-window of the Trend.

In the case of a long-term Trend,
if the price is continually going up
what is the Norm, in that Context?
It must be going up too,
but it's still going to be ploted as 0.
Z-Scores can be misleading in this situation.

Thanks's for that tip, I never realized this.

====

I've tried to build your ZScore system.
Letting TS optimize for the best Thresholds
between -2 and +2.

Results were very interesting.

I found there were several way to
set up Entry and Exits,
whether or not they had "common" or
"independent" Threshold Search spaces.

Here were the best Results I could get, so far:

TRADING STRATEGY #4

Theory_Z-2SD-Z+2SD 014_C INTC Implement3 TS4 19.cht

Intel Corp:OTC (INTC)
19% Annual Profit (last 24 months)

TRADING RULES { Optimized for ((W-L)*Profit) }

BUY LONG CONDITIONS:
CrossAbove(ZScore(Price-4,15),Mul2(1,1.41)) < Go Long >

SELL LONG CONDITIONS: [1 of which must be true]
CrossBelow(ZScore(Price-4,15),Mul2(1,1.66)) < Same as Go Short >
CrossBelow(ZScore(Price-4,15),Mul2(1,-2)) < Stop Loss >

SELL SHORT CONDITIONS:
CrossBelow(ZScore(Price-4,15),Mul2(1,1.66)) < Go Short >

COVER SHORT CONDITIONS: [1 of which must be true]
CrossAbove(ZScore(Price-4,15),Mul2(1,1.41)) < Same as Go Long >
CrossAbove(ZScore(Price-4,15),Mul2(1,0.75)) < Stop Loss >

I'll have to keep exploring this.

ZScores2-2_SineReversals.zip

(Zip File contains SD -2 to +2 Zscore ranges.
plus the Tangent Reveral analysis xls, described below)

==========

Mark, you mentioned another useful probability indicator

"Probability of a Turning Point" which sounds intriguing.

(any hints on how to do this would be appreciated)

I've noticed that with a "smoothed" momentum indicator
you can usually find the Tops (Bottoms) (ie Turning Points)

by taking the 1-Day Velocity
and looking for it to go
from Positive to Negative for Tops
and from Negative to Positive for Bottoms

Top: CrossBelow(Velocity(MomOsc,1),0)
Bottom: CrossBelow(Velocity(MomOsc,1),0)

The smoother the Momentum Oscillator the better the reversals
(smoothing without introducing lag seem to be
the "ultimate" trick needed here)

[BTW Ehler's Book: "MESA and Trading Market Cycles", pg 50-51

describes a cool way to do just that,
get a 0-Lag Smoothed Momentum Indictor.
But it requires Variable Window Indicators for SMA & Momentum,
with the Window parameters equal to the QuarterCycle;
I've built the DLLs for this with PowerBasic,
with very promising results, so far.]

Anyways, back to Velocity Reversal points,
I started to examine this using SineWaves in Excel.

When I take the Ratio of

(CycleMax - CyclePoint) / Velocity(CyclePoint,1)

I notice something VERY interesting:

Just before each SInewave Bottom (conversely Top)
there is an "early warning" of the Pending Reversal:

One day before the Sine actually reverses
This "Converging Tangent" Ratio grows to at least 3 times
it's previous value, sometimes there is a 10-fold increase,
immediately afterwhich the Ratio Reverses signs.
(ie. It has crossed the Zero-Slope Tangent,
and starts to head back "uphill")

Note: in the days leading up to this Bottom Reversal,
the 1-Unit Deltas of this Ratio, just grow GRADUALLY,
less than (1.0 * Previous Ratio).
And then suddenly explode: (3.0+ * Previous Ratio)

I've many a few attempts to re-build this as an Indicator,
against market data, with little success so far.
either the My Cycle Max windows are off,
or the inherit Lag in the Hilbert Dominant Cycle
is interfering with the Indicator precision.

SO My current Quest IS to build
a Zero-Lag or Low-Lag CYCLE Inidictor,
by measuring Phase Angles,
and extrapolating the angle to CycleLength.
I'm making good progress with this.

anyhow

thanks for your feedback
talk to you later.

By following up on the above example and applying what we discussed in earlier threads, a logical consequence would be to try to predict the ZScores indicator with a TDNN.

Theory_Z-2SD-Z+2SD 099_C INTC Test (data saved).zip

At first sight the Out of Sample signal seems to look promising with a Correlation(r) of around 0.5, but a closer look will evidence the introduction of a nasty lag. To be precise a lag of 4 days, which corresponds to the number of days we attempt to predict in the future. Another observation is that the lagged inputs do not contribute to a better result. Any moving average would do a better job! What is wrong here?

Thanks, Marcel

It's important to remember that when using the Z-Score, we're looking for a contrarian
position on a threshold being reached. I.E. When we reached +2SD we might want
to go short. When we reach -2SD we want to go long. (bear in mind 2SD is a little on the low side).

I.E. You're building a NN to predict Z-Score in the chart you provided. However most
of the time Z-Score isn't too meaningful, it's only at the extremes that we're interested.
An NN learns the data you provide it and not a subset of it, unless you specify the subset only (i.e. exclude the rest) by some other means.

I understand what strategy makes Z-Score interesting, i.e. to look for extreme values (+/- 2SD) that make a turning point highly probable. I have also to admit that it's not to meaningful to build a NN to predict Z-Scores - well, it was just another experiment... Btw, the NN did really a great job (this with reference to building a NN to learn a RSI)!

But the reason I wrote the above was because of that 4 bars lag that gets introduced when plotting on the same chart the Actual signal and the Out of Sample signal. It's a pure technical question that I can formulate also as follows: Why does the Actual signal get shifted to the left by the number of predicted bars in future? It seems to me that the engine does this for learning purposes - but "Actual" means exactly the one that is occurring, so why shift it?
Maybe it's up to Ward Systems to reply...

Regards, Marcel

Re: Z-Scores Hunch some Follow-up Tests

Date :8/10/2005 5:07:34 PM Poster : Ward.net Webmaster

The Actual signal is not shifted differently than the Out-of-sample signal. Both are plotted on the bar dated when the prediction is made, not the day the prediction is to come true. Both are for the same number of bars into the future. You may be seeing some other effect, like the one described in the tip on this site by this name:

What If Your Predictions are Just Time Lags of Your Actual Output? (OR Another Reason Not to Predict Close) (8/31/1998)

I was confused by this initially too.

I believe these NST Help Topics
may explain what's going on:

Cheers

James

Tools Menu

Options Choice

Predictions Tab

Help on this is:
==========

Use the prediction options to select which data series get displayed when completing a prediction and which data series to display in the Existing Data/Calculations list.

For more information regarding the prediction data series versus the prediction signal data series refer to Using Predictions.

Choose the Insert new prediction settings:

· Insert prediction signal data series – After you have finished creating a prediction, using this option will display the prediction data series on the chart with predicted data values on the same bar they were predicted (For example the 2-day prediction for July 5th would be shown on July 3rd.). This results in predictions that can be used in other indicators or trading strategies prior to the actual result occurring.

· Insert prediction data series – After you have finished creating a prediction, using this option will display the prediction data series on the chart with predicted data values on the bar for which they are being predicted (For example the 2-day prediction for July 5th would be shown on July 5th.). This results in prediction values that can not be used in other indicators until the actual result is already know. This also results in the prediction values being displayed on the chart on future bars that have not yet occurred.

Select Existing data/calculations settings:

· List walk-forwards and current network data series - shows all of the walk-forwards and current network data series in your Existing data/calculations settings.

· List prediction data series - displays both the prediction and the prediction signal data series. If not selected, then only the prediction signal data series will be displayed in the Existing Data/Calculations list.

==========
Help on:

Using Predictions

NeuroShell Trader produces two versions of a prediction, a version meant to be displayed on charts that is labeled "Out of Sample" and a version meant to be used as input to predictions and trading strategies that is labeled "Out of Sample Signal".

When adding a prediction to a chart or creating an indicator to be displayed on a chart, you may want to use the "Out of Sample" version of a prediction. The reason to do this is so that all predictions and indicators with predictions as inputs, will be placed on the graph at the date in which it is being predicted for. Doing so aligns the predictions to the actual prediction line for easy comparison and enables the prediction line and indicators based upon the prediction to extend out into the future.

When adding a prediction to a trading strategy/prediction or creating an indicator to be used in a trading strategy/prediction, NeuroShell Trader will only allow selection of the "Out of Sample Signal" version of a prediction. It does this so that when the prediction is used as an input, you are using a predicted future value on the day it is predicted instead of an old predicted value for the current day.

Having these two versions of a prediction available may create a problem if you try to add an indicator from your chart that uses an "Out of Sample" prediction as one of its inputs to a trading strategy or prediction. You should not add this indicator as an input because the indicator displayed on your chart contains the "Out of Sample" version of a prediction. Instead you should rebuild this indicator so that it uses the "Out of Sample Signal" version of the prediction. By rebuilding the indicator, you will be using a predicted future value on the day it is predicted instead of an old predicted value for the current day.

I always feel a little uneasy with the concept of a Dominant Cycle.
I believe there are times when a primary cycle that is bigger than the others
does exist, but they are small instances in time, and many of the other times we
see a DC, it's a few cycles superimposed. And as you suggested because of the lag,
it can be quite often gone before it's spotted.

So though I see spectrum analysis as a good solution to HUP (assuming you use
the correct kind of spectrum analysis), I don't see assuming there's one frequency instead of a spectrum is the best thing to do. I.E. DC is kind of a half way house
between non-adaptive and a spectrum analysis where we're assuming there's only one component in the spectrum (or another way of looking at it, is an adaptive indicator)

Although obviously the concept of 1 frequency is certainly better (and more adaptive), than just a regular indicator that is fixed in period.

The other issue is detecting all frequencies instantaneously without normalizing time
means that you don't have any longevitity. I.E. The underlying time base (the rate
of trading in our case) is changing constantly and doesn't persist for long, generally
by the time you've measured it, it's gone. We'll talk about this when normalizing time
(later discussion). You'll see that by fixing the time issue first, all most all indicators (including things like DC, will perform better).

Mark

I've agree with you and I also:

"feel a little uneasy with the concept of a Dominant Cycle.
I believe there are times when a primary cycle that is bigger than the others
does exist, but they are small instances in time, and many of the other times we
see a DC, it's a few cycles superimposed."

as you summarized quite nicely.

It seems only "natural" that several different cycles
are occurring simultaneously,
even if only due to the different "time horizons"
of the various traders and particpants in a market
(Day, Swing, Short, Intermediate, Long-term views, etc).

The KST (thanks to M. Pring) seems to
address these "sub-currents" nicely.
I've gotten very good NN results with KST,
after letting the NN find the appropiate window lengths,
for each time horizon.
However, seemed too much like curve-fitting,
and usually did not project forward well.

I've been focused on Hilbert DominantCycle lately
largely because of Ehlers [Cybernetics p 108]
when he insists/believes:

"Although all this is going on with cycle components,
the enduring characteristics is that generally
only one tradable cycle at a time is present
for the data set being used. I [Ehlers] prefer
the term Dominant Cycle to denote that one component."

I use his Hilbert DC code extensively, but it does
have many drawbacks:
1) Lag (4-8 days, depending on the reference)
2) doesn't handle trends well
3) is based on the differential on H & L of current bar (why these)
4) uses 5-bar Median smoothing to dampen Phase Angle noise.
5) ignores Neg. Phase Angles (calls it going backward in time)
6) Hilbert Sampling algorithm is poorly explained.
7) Ehlers does not address sub-component frequencies.

But the alternative Fournier Transform
which can find the SubComponents that make up a Cycle,
has an assumption for "stationary dataset"
(ie all the sub-component Cycle Lengths
will remain fixed over time.
This is hardly a given in market data.)

I've found Hilbert DC a good "generalization" and model,
and it has helped me learn the Cycle Math involved.
And I'm hoping to improve upon it, myself.
In the meantime I've got to use some sort ofcycle detection.
(I've alos been looking to Channel Breakouts, as an alternative,
and a "lag-less" way to tell a Trend may be starting,
and conversly a Cycle is ending)

This weekend I determined the algebraic solutions
to calcing the 1-day lead to any 2 component SineWave
(its just an idealized solution, for now,

using noiseless data of 2 sine waves, but its a start)
The calced Lead follows the component curve perfectly,
and requires as inputs only the "Cycle Lengths"
and "Amplitudes" of each Sub-component.

and it appears the Lead can be adjusted
forward all the way up to a half cycle lead.
(a 10-day Lead, where the min CycLength is 20-Day)

Mark, thanks for taking the time to
go over my posts
and for the helpful Feedback

James Siebert

The formula has SMA's in which introduce lag. This is an example of
a normal multiple time frame system. Essentially you can use multiple time frames
to resolve some of the uncertainty about direction. The only issue is that the longer time frames have more lag. Still MTF'ing a system is better than not.
Also check out:

http://www.dspguru.com/info/faqs/fir/basics.htm

you can design FIR and IIR filters that you can easily implement in NST which
have similar properties to things like KST and some of the ones sold as zero lag or near
zero lag moving averages.

MTF'ing however comes back to a similar discussion about cycles. I.E. Is 3 timeframes really enough?

>I've been focused on Hilbert DominantCycle lately
>largely because of Ehlers [Cybernetics p 108]
>when he insists/believes:

>"Although all this is going on with cycle components,
>the enduring characteristics is that generally

>for the data set being used. I [Ehlers] prefer
>the term Dominant Cycle to denote that one component."
I've always had an issue with this one. I'm not downgrading Ehlers
work by any means, he does superb and sound analysis, and I recommend
people read his books as he has a non-conventional approach. However I do have
issue with the DC, because an FFT
will show a spectrum at many frequencies. Even if you can see a clear cycle going on,
you'll notice there's normally at least a longer term cycle superimposed on top.
In reality a clear cycle would be traded out virtually immediately, so the next
issue becomes detecting a cycle before it's gone.

>I use his Hilbert DC code extensively, but it does
>have many drawbacks:
>1) Lag (4-8 days, depending on the reference)
>2) doesn't handle trends well
A trend can be viewed as a longer term cycle. Hence multicycle activity which
hilbert can't resolve.

>3) is based on the differential on H & L of current bar (why these)
He doesn't say in his book, but he's likely using (H+L)/2 for noise reduction.
You could use anything here, even (O+H+L+C)/4 for slightly better noise
reduction.

>4) uses 5-bar Median smoothing to dampen Phase Angle noise.

>5) ignores Neg. Phase Angles (calls it going backward in time)
My advice is not to ignore Negative Phase Angles. Time going backwards can
be very indicative of events.

>But the alternative Fourrier Transform
>which can find the SubComponents that make up a Cycle,
>has an assumption for "stationary dataset"
>(ie all the sub-component Cycle Lengths
>will remain fixed over time.
>This is hardly a given in market data.)
You can also use a windowed FFT to sample non-stationarity. However you still
need the start and end of the data to start at 0, and the end point is precisely the
point we need the most precision, which normally meanse you have to
throw FFT's out of the window.

I did have a statistician friend of mine once suggest that instead of applying a
hanning window to the data before FFT'ing it, if you imaginged price on the usual
horizontal line, then you could rotate the 2D plane to make price start/end at 0.
(obviously we'd be dealing with Z-Scored price or some other normalization).
I abandoned that idea purely because it would add noise to the FFT which
I didn't have enough knowledge about the math involved to remove, however it
might be worth a try for you (let me know how you get on with it, if you do).

That shape looks very similar to a sigmoid or hyperbolic tan function rotated
90 degrees. Also if you check out the tan function and mirror it, it looks
similar.

http://mathworld.wolfram.com/Tangent.html

Price distributions aren't normal, and you want bigger sensitivity in the extremes.
I.E. Your indicator provides greater sensitivity at the turning points of the sine
wave, which is better than assuming normality.

How does it do on real data?

Bowfort Technologies Inc.

Re: Z-Scores Hunch some Follow-up Tests

Date :8/8/2005 1:17:43 AM Poster : James Siebert

> How does it do on real data?

That's the Problem,
Seems that real data is too noisy
and jumps past or obscures the "early warning"

However I think I gave up on this too quickly.
It occurred to me later,
that the way I was finding the "previous max" was "flawed"

I should not be using a "fixed window" Price High Lookback
but a "variable window" Max function.
(once against how far to look back for the max is problematic)

What's the time horizon of the "immediate cycle"?
My early warning calc is subtracting against
this "high water" mark, which is no problem in a Sine Wave.

But in market data when is the recent high
"too recent" or not "recent enough"

So I'm forced to go back to Hilbert DominantCycle again to tell me
the "just right" Lookback window, (or likely: 1.5*HDC Window)

But is this accurate enough to peg the recent top?
Not sure, will have to check it out some more.

The early warning idea seemed interesting
and has potential if anyone can figure out
how to get a handle on it. That's why I posted it.

Thanks again for the feedback

(I was thinking if might be related to the arctan,
or something like that,
especially with the Infinity as one reversal,
an the Zeros at the other.)

James

>(ie. It has crossed the Zero-Slope Tangent,
>and starts to head back "uphill".)

That shape looks very similar to a sigmoid or hyperbolic tan function rotated
90 degrees. Also if you check out the tan function and mirror it, it looks
similar.

http://mathworld.wolfram.com/Tangent.html

Price distributions aren't normal, and you want bigger sensitivity in the extremes.
I.E. Your indicator provides greater sensitivity at the turning points of the sine
wave, which is better than assuming normality.

How does it do on real data?

Re: Z-Scores Hunch some Follow-up Tests

Date :8/2/2005 7:18:34 AM Poster : Marcel

James,

I've gone through your example step by step. It was interesting to follow someone else's approach, and to see that more and more substantial knowledge is shared in this forum.

I took the opportunity to learn a bit more about Z-Scores, from my perspective yet another way of generating a valuable and useful signal. From my experience however, models based on traditional trading strategies (like crossovers, breakouts etc.) are limited in nature. Yes, you can optimize (curve fit) them to work particularly well for certain instruments or market situations, but when you try to generalize or adapt them to broader or longer market conditions, they miserably fail to deliver the expected performance - at best you can cover your expenses. I base this observation a) on a large number of tests I've done myself, and b) on the simple fact that if this perfect conventional model would exist, it would have been found by someone else years ago...

That's the reason why I'm taking a second chance with NN's. If we learn to correctly apply the predictive potential inherent to NN's, I think we are a) moving onto a ground that is pretty unexplored and untested by thousands of predecessors (mainly due to the unlimited number of concepts one can implement), and b) adding a powerful and promising technology to the traditional trading strategies (hence an enrichment, complimentary).

The journey that Mark is taking us thru is paramount to achieve this goal, in my opinion we have a unique chance to learn and discuss principles and concepts that no book or lesson can teach.

Best Regards,
Marcel

WELL I did just that ...

This Trading System and its NN-tuned Threshold parameters
seem to be "generic" (at least generic for "tech stocks" anyways)

Here are the results from my quick follow-up tests

ZScore_Theory_followup_tests.zip

004_a AMD 32%
004_a MSFT 14%
004_a NVDA 84%
004_a ORCL 14%
004_a SUNW 24%
004_a SYMC 30%

Perhaps I was too quick to post my Z-Score Theory. (LOL)

I threw it together yesterday as an Example exercise.

Did not realize it might be conisistently profitable,
se la vie.

Feel Free to use the Theory,
to improve upon it and to use for trading.
(my contribution to the Forum,
and the "free exchange" of Ideas.)

Let me know what improvements you come up with.

If you strike it big with the Z-Score Cross System,
drop me a Post Card.

This model that James is talking about is a conventional model being used with
unconventional thinking. I.E. Crossovers can work if you have zero-lag indicators.
And it will work on most things too. Quite often you can use conventional models in
unconventional ways and get them to work if you consider the lag issue.

>That's the reason why I'm taking a second chance with NN's. But don't overate the NN, they are a very useful tool, but only a part of the package.

I'd say 50% is thinking about how to design good models, 40% is building your
good inputs, and 10% is about the NN. The NN just saves a lot of work in figuring out
the meaning of the 40%.

That's an interesting comment, I had given up completely conventional models with the reasons I mentioned above. So let's discuss "unconventional ways". Are these linked/limited to the paradigm of feeding zero-lag indicators? Are there other tricks we should be aware of?

Do you build models that make no use of NNs? Models that are solely relying on Trading Strategies?

Thanks, Marcel

There are many ways. You can use conventional models in unconventional ways, or
you can just be unconventional from the start. But it all hinges out of
truely understanding lag, and the model design, once you have that beat,
actually doing it is relatively simple.

Yes I do. I only use an NN if the relationship isn't obvious and if it's necessary.
An NN is like any other tool, there's times when you need it and times when you don't.
If you can't figure out a function, then the NN does it for you.
Incidentally it's always worth running through an NN on paper (or
NST's neural network training example I referenced earlier), just to learn how simple
NN's are in concept and how a simple concept can generate something so powerful.

Mark – thanks v.m. for the feedback, really appreciate.

Now a personal comment to the Forum:

I'm honestly getting a bit lost with Z-Scores, Horst etc. The main reason is that my knowledge about statistics is pretty rusty, since I never had the chance or necessity to make use of it since I left university – many years ago. I don't know what other fellows feel, but for me in order to keep up with this thread, I need to go back pretty far to the basics, a lot of effort that prevents me from contributing or adding any value to the discussion.

I don't want this thread to stop, please continue as much as needed. As a silent reader, I will do whatever I can while refreshing my notions of statistics. On the other hand, there are a number of other discussions that have been left suspended, and that I would appreciate to see resumed.

On top of my head some examples:
- Classes of indicators that work, and why they work
- How to identify the rest that don't and maybe a bit about how to fix them
- Teach a NN to learn RSI or any other indicator
- The curve fitting discussion
- Normalizing time; by fixing the time issue first, most indicators will perform better
- Filtering (DSP) techniques in our models

Thanks a lot!
Marcel

Yes we have side tracked a bit. But lets just summarize this a bit and bring it
back in scope to avoid some confusion. This is because Z-Score in particular
is a pretty useful thing to use, so we don't want to throw it out.

I'm deliberately simplifying it for description purposes.

Essentially Z-Score is nothing miraculous, it just measures probability, another
way of thinking of it is like this:

Zscore is a measure of how rare the value of bar is compared to the bars in window
(periods). I.E. If price was meandering around a 2% range, and then suddenly jumped up or down by 10% in either direction, then a jump down might be flagged as a
low zscore of say -3 and a jump up might be flagged as +3. The 2% range might be
a zscore in the range -1 to +1 as the stock moved around in the -1% to +1% range (i.e. a 2% range). I.E. You can think of more extreme values of zscore as measuring
improbable or unusual events.

It also doubles up as normalization, i.e. bringing things into a reasonable range and
centered around zero.

Another approach to z-score is that the more extreme the value is, the more likely the
data point is meaningful, and that at some point it's likely to return to normal.
I.E. If we go down one day by 10% in price, and Z-Score signals -3, then the following
days it is quite likely to want to head back (things don't go straight up or straight down
more often than not).

So if you got a value of say -1 to +1, then you would say that it was a pretty normal occurance. -2 or +2 would be less frequent, -3 or +3 would be even less frequent and
so on.

The periods in the Z-Score should be set to something that is a reasonable sample
length, i.e. a good number of bars, generally in the 100-300 range, you want to
capture some history so you can see what's abnormal, but not too much, that
abnormal becomes normal.

Now onto hurst. ZScore assumes normality, all that is, is when you plot say
returns of price on a histogram (technically log returns, but lets keep it simple), that
the histogram follows a certain shape, often known as the normal distribution or the bell
curve. Most random processes follow this same bell curve and it's just a statistical
way of saying, well, something is normal. If the stocks were random, then they would
follow this same bell curve.

However, the curves follow something called a Hurst Distribution more closely. All
a hurst distribution is, is a bell curve with fatter tails. I.E. The more extreme values
in return in price would be more frequent than a random process would suggest.
Hurst spotted this when analyzing flood data in the Nile, i.e. it wasn't a normal
distribution, and he formalized this kind of data.

So, the question becomes, is a ZScore right to use? The answer is yes. However
a Hurst distribution would give a slightly better model, which is why the discussion
started about building a Hurst Score. It's not needed for this by any means, but
it's some interesting research.

>On top of my head some examples:
>- Classes of indicators that work, and why they work
>- How to identify the rest that don't and maybe a bit about how to fix them
>- Teach a NN to learn RSI or any other indicator
These ones we've already discussed to some degree. So lets finish off these.
Over to you guys.

>- The curve fitting discussion
>- Normalizing time; by fixing the time issue first, most indicators will perform better
>- Filtering (DSP) techniques in our models
Lets finish off the top 3 first before going on to these. There are a lot of messages
so far, and with many discussions going on it's getting a little confusing.

Marcel

Thanks for the feedback,
and taking the time to look at my Charts.

I tend to agree with you regarding
"generalized" solutions.

If there was a "Golden Goose" Trading System,
someone (or overuse) would had squashed by now.

I like the metaphor of "Supply and Demand better.
If and when "inefficiencies" exist in a Market,
an alert observor can take advantage
of an inefficieny, until it becomes "common knowledge"
and the overall Market adjusts accordingly.

When this happens, the "edge" evaporates.

There was a day when SMA(20) - SMA(50) Oscillator
was a "killer system". Not any more.

The Fact that SMA(200) acts as the final support level,
is because everyone expects to be such.

Usually, if the Price punches thru 200 day average,
look out, as you can expect the "bottom to fall out."

This "inefficiencies" theory, I believe,
is main reason it is so hard to find
a good Trading System using the QQQQ or MSFT.

These stocks are so "high profile" that
any "market inefficiencies" there were found long ago,
by someone, (several someones)
and are already be accounted for, in the current behavoir

I think however such "inefficiencies"
likely exist in other "unpopular" markets,
which do not get the same level of scrutiny
as the MSFTs of the world. The problem with
such "below the radar" stocks is that they
may not be liquid enough to support
reliable patterns and signals.
(another area to research, how to identify these)

Marcel, one more observation I would make,
and this has been the focus of much of my latest research,
is that "traditional trading strategies
(like crossovers, breakouts etc.)" you refer to
can be leveraged back to life
by applying them SELECTIVELY.

When combined with a Good "Market_Mode" Indicator
a traditional system can work surprisely well.

A "Market_Mode" Indicator attempts to tell you
if the Price Series is behaving in
Cycle_Mode or Trending_Mode. (aka. Range-Bound vs Breaking Out)

The Selection Rule is:
Use a "Momentum Reveral" System while in Cycle_Mode.
Use an "Average Oscillating" System while in Trend_Mode.

The catch here, is finding a Good "Market_Mode" Indicator.
VHF is one, Ehler's MESA is another,
Elher's Hilbert Dominant Cycle also helps,
Murray Ruggerio has yet another custom indicator
to detect Cycles.

But they all have problems.
Yet as imperfect as they are,
I believe they still give you that "edge"
that the average market participant does not have.

I'm working on my own Cycle Detection system now
that hopefully while have minimal Lag, when perfected, (fingers crossed)
and provide an edge over other "Market_Mode" Indicators,
if even for only a short while, until similar
Indicators are constructed by other participants.

Marcel as you note, NN is new ground,
and represent unexplored territory,
who's promise is
that may hold untapped resources (ie. "inefficiencies").
They won't say under-utilized for long,
with great tools like NS which make NN math accessible,
to average traders.

The ray of hope here though,
is that with N-Dimensional ways of combining
input signals, and the likely limitless possibilities
for finding NN Solution Spaces,
the chance of NN have a "self correcting" on a market and
due to "common knowledge" factor, is less likely.

That's my take anyways

Cheers,

James S.

Try plotting a distribution of log percent returns of the market. You'll
initially think it's normal, but if you look closely, you'll see the tails are considerably
fatter. The opportunity is still there, and it's in the tails, you just have to find it, and it's
not what the majority are doing. This is partly the reason I don't provide a complete
trading system that works, more ideas that can be put together. Essentially
if you provide a trading system, and it's used by enough people then the opportunity
will be traded out, however many people with different systems still leave the
potential there.

However as skills improve overall and analysis progresses, I'm sure years into the
future the techniques we're learning now will no longer work, so it's important to keep
on top of things.

Mark

Thanks again, I've read a little bit about
"fat tails" distribution (Hurst distribution,
1st seen in patterns of Nile River Floods)
but never realize that the tails
"were the profits were".

("Fat Tails" are roughly equivelent to
seeing many more Event occurrences > +-3 SD,
than one should expect when data has "Normal" Distribution
[a Bell-Shaped curve, due the "laws of averages',
and will Normally have "skinny tails", few events >|3|.])

"Fat tails" in the data imply that at the Extremes,
other behavoir is kicking in besides the "laws of chance".

If true, How does this effect your
Contarian Z-score return to the Norm system?
It would seem there might be a profitable"trading zone"
between 2 and 3 (4?) SD if "Fat tails" are normal situation?

I like you're focus on tools over systems,
that tends to be my focus as well.
You can tell a "good carpenter"
by his adeptness with a wide variety of tools.
And by the number of tools in his toolbox.

My boss has a saying,
meant to promote creative problem-solving:

"If your only tool is a hammer,
then every problem looks like a nail"

IE. what other Tool might work?

>>The catch here, is finding a Good "Market_Mode" Indicator.
>>VHF is one, Ehler's MESA is another,
>>Elher's Hilbert Dominant Cycle also helps,
>>Murray Ruggerio has yet another custom indicator
>>to detect Cycles.

>Also check out entropy type indicators and fractal dimension.

I have an interest in both of these topics,
but as of yet have been unable to find practical ways
to apply them to Market Time Series Data.

Although, I was starting to see some Fractal patterns
in my 4-Cluster Analysis system,
alluded to in my Correlation Xls (at bottom)

I was observing the sequence of event hits
striking within each Cluster circle,
seemed to "bunch together" in
into "tiered signal blocks" as Events
alteranated between Clusters
(ie was not random,
could see Trend Changes forming, like Clouds on the horizon)

Mark, thanks again for your insights and direction.

Sorry, my last message yesterday had so many typos,
I did not have time to proofread it. (I got a day job)

Be kind when you evaluate my "quiz answers".
The "physics of zero-lag" is still quite new to me,
and I'm learning more about this daily.
I took a shot, given what I "think I know" now.

Thank for putting together such challenging questions.

Best regards,

James S.

Yes, that's correct, it is similar to Hurst, and Fat Tails are the norm. You
only have to look at market crashes, and other major movements in price to see
that some of would be extremely infrequent (thousands or millions of years)
based on a normal distribution. However in real life they happen a lot more frequently.
So that said, you look for the fat tails, and trade those.

Z-Score models it okay if we bear in mind extreme values happen more frequently
than normality. Maybe we could figure out a Hurst Score instead of a Z-Score?

When we normalize time, this will start dropping into place.

>Z-Score models it okay if we bear in mind extreme values happen more frequently
>than normality. Maybe we could figure out a Hurst Score instead of a Z-Score?

I like that idea, "a Hurst Score instead of a Z-Score"
I'll have to put that one
on my to-do research list.

---
no time like the present...

to kick off this Hurst subject
here is the "best" reference
I have which tries to
define Hurst exponent/distributions

(Note: it seems to be
trying to "normalize"
the scale of phenomenon Magnitude against
the scale of time horizon for counting
those phenomenon Events.
I'm imagining Earthquake Size vs Frequency.)

Here's the text:
==========
The quantity in question is the "rescaled range R/S",

which is essentially the range R(Delta-t) of the data
over the time interval Delta-t. ...

For a white Gaussian noise,
the ratio R/S tends to be constant, for large Delta-t.

In a sense , both R and S measure
the range of data,
but R "looks" at the data linearly
and S is based on the squared data.

For some processes this yields no new information
and R/S is ... constant, that is proportional to Delta-t^0.

This is not so for numerous geophysical records,
such as floods, ...

For a Brownian function
R/S is proportional to Delta-t^0.5,
reflecting the long-range dependence,
or "persistence" hiding behind the brown process. ..."

[Scatter charts:

X: Time (Log scale: 1 to 10000)
Y: "R/S" (Log scale: 0.1 to 1000)

Event Points: such as Floods
tend to fall on a diagonal line
which has the slope of the Delta-t Exponent;
Example: the records of Nile River Droughts
for instance has a slope of 0.9]

"The Hurst exponent, defined by

H = log(R/s) / log(Delta-t),

is a convenient measure of the persistence of
statistical phenomenon."

==========

["Fractals, Chaos, Power Laws" M. Schroeder, pg 129-130]

Clear as mud eh?

Isn't technical math fun?

Seems like this may have something
to do with normalizing events on different Time Scales?

It seems the linear lines in the R/S vs Time plots
are "ironing out" what we normally consider
jagged Fractal Phenomenon into what appear
to be "straight lines".

Yes, that's correct, it is similar to Hurst, and Fat Tails are the norm. You
only have to look at market crashes, and other major movements in price to see
that some of would be extremely infrequent (thousands or millions of years)
based on a normal distribution. However in real life they happen a lot more frequently.
So that said, you look for the fat tails, and trade those.

Z-Score models it okay if we bear in mind extreme values happen more frequently
than normality. Maybe we could figure out a Hurst Score instead of a Z-Score?

some more geeky details
on Hurst Distributions

Definition:
==========

Hurst Exponent: A measure of the bias in Fractional Brownian Motion.

H = 0.50 for Brownian motion.

0.50 < H < 1.00 for persistent, or Trend-reinforcing series.

0 < H < 0.50 for an anti-persistent, or mean-reverting system.

The inverse of the Hurst exponent is equal to alpha,
the characteristic exponent for Stable Paretian distributions.

The fractal dimension of a time series, D, is equivalent to 2-H.

from
http://financial-dictionary.thefreedictionary.com/Hurst+Exponent

==========

Concpetual Description:

==========

2.1. "Fractal" Dynamics

The statistical paradigm against which the sequence of increments
from a chaotic dynamical process
is typically contrasted is that of a white noise process.

"White noise" typically refers to a sequence whose increments
are independently and identically distributed
with zero mean and finite variance.

Brownian motion, a well-known paradigm in finance,
is a white noise process for which
the independent increments are identically normally distributed.

A fractal time series is one which is statistically "self-similar"
(apart from scale) regardless of the time frame
over which the increments of the series are observed.

For example, a sequence of daily observations
would exhibit similar statistical characteristics to
sequences of weekly, monthly, or yearly observations,
and the scale of the observations
would be a direct function of the length of time involved.

Brownian motion, as a white noise process
which exhibits these time series properties,
is as Schroeder (1991) notes,
"the paradigm of random fractals."

However, during the 1960's Benoit Mandelbrot,
"the father of fractal geometry", believed that
securities returns did in fact follow a fractal time series
but that Brownian motion was not an adequate statistical description
of the true stochastic process generating securities returns.

In order to resolve this inadequacy,
Mandelbrot worked in two perpendicular directions to expand
the class of fractal time series.

One direction involved relaxing the assumption of finite variance,
which introduces what Mandelbrot termed the "Noah Effect."

The other direction entailed relaxing the independence assumption,
thereby allowing for a "Joseph Effect."

The Joseph Effect (see Mandelbrot (1972)) is named after
the biblical story in which Joseph
prophesied that the residents of Egypt
would face seven years of feast
followed by seven year of famine.

This effect denotes the property of certain time series
to exhibit persistent behavior
(such as years of flooding
followed by years of drought
along the Nile River basin)
more frequently than would be expected
if the series were completely random,

but without exhibiting any significant short-term (Markovian) dependence.

To describe such processes, Mandelbrot broadened the idea of Brownian motion
into the class of stochastic processes
called "fractional" Brownian motion (fBm),

or, using the noise analogy, "flicker noises."

Fractional Brownian motions exhibit complex,
though linear, long-term dependencies
and are characterized by a parameter called the Hurst exponent (H),

which denotes the level of long-range dependence in the data
and generally ranges from 0 to 1.

If H=0.5, then the fractional Brownian motion will
have no long-term persistence,
and the result is standard Brownian motion,
or white noise.

I like that idea, "a Hurst Score instead of a Z-Score"
I'll have to put that one
on my to-do research list.

---
no time like the present...

to kick off this Hurst subject
here is the "best" reference
I have which tries to
define Hurst exponent/distributions

(Note: it seems to be
trying to "normalize"
the scale of phenomenon Magnitude against
the scale of time horizon for counting
those phenomenon Events.
I'm imagining Earthquake Size vs Frequency.)

Here's the text:
==========
The quantity in question is the "rescaled range R/S",
which is essentially the range R(Delta-t) of the data
over the time interval Delta-t. ...

For a white Gaussian noise,
the ratio R/S tends to be constant, for large Delta-t.

In a sense , both R and S measure
the range of data.
but R "looks" at the data linearly
and S is based on the squared data.

For some processes this yields no new information
and R/S is ... constant, that is proportional to Delta-t^0.

This is not so for numerous geophysical records,
such as floods, ...

For a Brownian function
R/S is proportional to Delta-t^0.5,
reflecting the long-range dependence,
or "persistence" hiding behind the brown process. ..."

[Scatter charts:

X: Time (Log scale: 1 to 10000)
Y: "R/S" (Log scale: 0.1 to 1000)

Event Points: such as Floods
tend to fall on a diagonal line
which has the slope of the Delta-t Exponent;
Example: the records of Nile River Droughts
for instance has a slope of 0.9]

"The Hurst exponent, defined by

H = log(R/s) / log(Delta-t),

is a convenient measure of the persistence of
statistical phenomenon."

Still researching Hurst thru Google.
starting to get to the real math behind it:

"Using the Scaling Analysis to Characterize
Financial Markets"

http://xxx.lanl.gov/PS_cache/cond-mat/pdf/0302/0302434.pdf

Be sure to check out the Conclusions and Appendix in the pdf

I'm beginning to think a "Practical Hurst Score"
might be obtained be tweaking the formula
for the Gaussian Normal Curve
(aka. Probability Distribution Function)
since the Z-Score actually measures the probabilities
under the various sections of this Curve.

http://amsglossary.allenpress.com/glossary/browse?s=p&p=64

The probability of Event x
occurring within a sample population, which has
a Gaussian Normal Curve distribution,
is given by this forumla:

p(x) = [sqrt(N) / (SD * sqrt(2*pi))] * ...

e raised to [[-N *(x - mean(x))^2] / [2 * Variance]]

where
Variance is Square(SD)
N is the sample size (ie Lookback window)
Mean is the SMA of x in the Lookback window.

Not exactly simple, but not rocket science either
Many of the terms can be created from NS Indicators.
Looks to me we just need to figure out
the "Hurst-way" to calculate Standard Deviation. (?)

Take for example,
The probability of Event x (say Price Move +$2)
given the last 30 days where the Price has
been range bound (+ or - $1) [the context]

A ZScore for this would likely be in the +3 Tail region,
(Because it takes 3x the Normal Variation [1SD] to get there)

however
What would the Event x 's HScore be?
if such "episodic" price run-ups,
though uncommon, are NOT exactly rare occurrences?

Since the H-Curve distribution is probably "squatter"
with "fatter" tails regions,
"a Price Move of +$2" should be MORE likely,
(easier to reach)
and may repeat in clusters, or in a "run-up" Epoch,
(similar to an era of "price gain floods" [or a breakout Trend])
(such price-run examples exist: Google, Taser, Ebay, etc.)

Given such a sample,
comprised of many "Epoch" price deltas,
the Mean may skew towards the + side,
and the H-Score may acutally be LESS than +3 SD (more like 2.5)
instead of greater than 3, with ZScore (given pure random population)

I've research "Skew" measures before,
and they definitely seemed to pre-clude run up periods
(or down periods for Neg Skews)

I'll let you know if I get anywhere with this

take care,

James Siebert

Re: Z-Scores; Hurst Distributions

Date :8/10/2005 12:32:47 PM Poster : James Siebert

some more "real math" on
Fractal Dimensions and

"Estimating the Hurst Exponent" (has lots of graphics)

http://www.bearcave.com/misl/misl_tech/wavelets/hurst/

It occurred to me also
that the Student's t-test

may be another way to
arrive at the same destination of calcing a Hurst-Score.

Since Student's t-test are designed
to give you Squatter Distribution Curves with Fatter Tails
(ie non-normal distributions):

Student's t-test (site has very good Intro to Stats)

http://projectile.is.cs.cmu.edu/research/public/talks/t-test.htm#glance
----

The actual Flood/Drought Epochs we see in Price data series

might be due to the "degrees of freedom" effect
used in calcing Student t Deviations ???
(which are always > 1)

The SD of a t Distribution is defined by:

df / (df -2)

for instance a t-sample of 10
has a SD of 1.28
[9 / 7]

by contract a "Normal" Gaussian Distribution has a SD of 1.0

just my creative thought, for the day. ;)

[Note: here's "degrees of freedom" conceptual example:

If I tell you I need an average of 5, based on any 4 random numbers,
What numbers can I use to get this result?

you can "freely" choose the first 3 out of 4 numbers for me
(say 8, 3, -2)
BUT that last number, given the 1st three,
IS NOT FREE to be anything.

IE the Last Choice is determine by the 1st Three Choices
aka
my sample of 4 Numbers, in this example, "has 3 degrees of freedom".
df = (n - 1)

Question: what must that last choice be?

(x + 8 + 3 + (-2)) = 20

x + 9 = 20

x = 20 - 9

x = 11

the average of (11 + 8 + 3 + (-2)) = 5

end of example]

Bottom line is ZScore assumptions
(data has 0-Mean, & Variations of 1 SD)

May NOT always accurately describe the Data Series in question
and a new way of calcing this comparison metric
may be approriate
(Hurst Exponent, Student's t-test, etc)

<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<

Hurst Research a progress report:
==========

Key Principles:

Time Series Price data
usually behave as if they are
in 1 of 3 Modes:

---

1) "Random Walk" Behaviour:

Hurst Exponent = 0.5

Model: Flip a "fair" coin (50/50 odds H/T)

H: Price = Price1 +0.25
T: Price = Price1 -0.25

Assumption is that today's price move
has "no memory" of yesterday's price move.

(consolidation periods are difficult to predict)

---

2) "Persistent" Behaviour:

Hurst Exponent = greater than 0.5, up to 1.0

Model: Flip a "weighted" coin (70/30 odds H/T)

H: occurs 7 out 10 times
Price moves in SAME direction as yesteray's move (+-0.25)

T: occurs 3 out 10 times
Price moves in OPPOSITE direction as yesteray's move (+-0.25)

Assumption is that today's price move
is positively correlated to yesterday's price move(s)

(trends tend to persist, and continue)

---

3) "Reversion to the Mean" Behaviour:

Hurst Exponent = less than 0.5, down to 0.0

Model: Flip a "weighted" coin (30/70 odds H/T)

H: occurs 3 out 10 times
Price moves in SAME direction as yesteray's move (+-0.25)

T: occurs 7 out 10 times
Price moves in OPPOSITE direction as yesteray's move (+-0.25)

Assumption is that today's price move
is negatively correlated to yesterday's price move(s)

(cycles tend to correct, and reverse)

Many researchers believe that stock markets

predominantly exhibit Hurst Exponents between 0.5 and 1.0.
(persistance behaviour, where prices
have some degree of "memory" or "momentum" of the recent past)

["auto-correlation" is the technical term, which uses
math that is similar to TDNN in concept]

This is supposedly due to Fractal properties of Time Series data,
when observed with respect to many different Time Scales.
(for example when comparing SMA(50) to SMA(200) etc)

Put simply:
Price Moves DO NOT usually behave like they are following
a "fair" coin flipping model. There is something other
than "pure chance" at work here!

(Of course we all knew this already,
or else we probably would not had purchased NST ;)

I'm currently researching how to measure the Hurst Exponent directly
as opposed to taking the Statistical Curve tweaking approach.

I discovered I needed to understand the metrics
and what was being sampled in Hurst analysis,
before I could see what to tweak within the Gaussian Model.

cheers

James Siebert

>Seems like this may have something
>to do with normalizing events on different Time Scales?
Correct. The math is ugly, but if you except the premise that markets are
fractal in nature, then you have to fix the time base first (normalize time)
before you analyze them with fractal tools.

Also, check out fractal D, it can be used to denote the complexity of the market
you're modelling. Essentially the higher the fractal D, the more variables you need
to build a model. Or alternatively just trade when fractal D is low for instance.

I.E. If you're sampling things, then you want to sample them on a regular basis.
People assume because a clock ticks on a regular basis, i.e. it's linear
process, then markets trade on the same basis and then they execute their
indicators on this linear timebase.

Or another way of looking at it is, if there was a river and we need to measure effects
on the banks of the river by erosion etc., would we get better result, by just sampling every minute, or would we get better results by measuring the flow rate and using
that to denote our measurement?

James,

Thanks for the additional comments and the directions you are giving wrt Market_Mode. I came to the similar conclusion years ago, but never could afford the time to further explore this path.

At this point in time, I however feel the need to make a few steps back, to simplify a bit this discussion and decompose it in digestible pieces: Let's assume that either a) we are focused on an instrument that follows purely a cycle (or a trend) mode, or b) we have a separate system that is able - for a particular instrument - to distinguish the cycle from the trend phases. How do we build the 2 subsystems that can independently and successfully generate signals for those two modes?

Personal note: When implementing a NN, sooner or later I find myself doing fuzzy "trial and error", and I'd so much like to manage the process in a more structured manner. In other words, I honestly don't yet feel comfortable of mastering the process and be able for example to build these 2 independent subsystems, so that they deliver expectable results. I may be looking for inexistent perfection, but I'm sure many other (silent) forum visitors are having (or had) this same experience.

Best Regards,
Marcel

Marcel

Here's the basic "floorplan" I've come up with
when I'm building a TS that can handle, as you say
"2 subsystems that can independently and
successfully generate signals for those two modes"
(both trend & cycle signals at the same time.)

The Stages: 1) get the materials, 2) build the structure:

1) At minimum, I get (build) 8 True/False indicators and

2) then combine them with OR & AND (Boolean operators)
to create signals which tell me
whether to Enter or Exit a position.

NOTE: this "Decison Rule" system is largely
the result of my 15+ years of programming for a living.

TS system may not look obvious at first,
and can take some tweaking, especially on the Exits,
But this methodology can result in "Mode Trades"
that do not step on each other, and work concurrently. :)

Of course the timelessiness of the Position Switches
based on the Mode Signal changes, will only
reflect the Quality of you Mode indicator.

(VHF is an easy one to start with; Vertical Horizontal Filter)

Get the materials:

====== Get at least 8 True or False indicators =======
====== Each of these Indicators should evaluate to 1 or 0

MARKET MODE ENTRY:

1) TrendMode = using your favorite Mode Indicator
2) CycleMode = using the same Mode Indicator

(I sometimes use "TrendMode = 0" to indicate "CycleMode".
It's important that the Trend and Cycle Modes do not overlap)

TREND ENTRY/EXIT: (will combine with TrendMode)

3) Bias_Long_SMA =
Is Price less than the SMA of Price?
(then likely to go up)

4) Bias_Short_SMA =
Is Price more than the SMA of Price?
(then likely to go down)

CYCLE ENTRY/EXIT: (will combine with CycleMode)

5) Reversal_Long = Did your Momentum Velocity just go from + to - slope (0)
6) Reversal_Short = Did your Momentum Velocity just go from - to + slope (0)

MARKET MODE EXIT: (use as Exit Signal only)

7) 1stTrend = If 1st Day of Trend: Exit any Cycle-based position
8) 1stCycle = If 1st Day of Cycle: Exit any Trend-based position

(these last 2 are harder to construct,
and to harder to see in action,
but basically these Single-Spike Flags
indicate the End of one Mode and
the Start of the next Mode.
(ie. time to close last "mode position",
and start the next one.)

==========

Build the TS Structure:

====== Combine the 8 True or False indicators =======
====== with Boolean Operators (AND & OR) ===========

NOTE: the combined Indicators must still
evaluate to either True or False, when
joined together in "Compound" Decision Rules:

LONG ENTRY: (any 1 is True)

TrendMode AND Bias_Long_SMA ====> (1 & 1) GoLong
CycleMode AND Reversal_Long ====> (1 & 1) GoLong

LONG EXIT: (any 1 is True)

TrendMode AND Bias_Short_SMA ====> (1 & 1) ExitLong
CycleMode AND Reversal_Short ====> (1 & 1) ExitLong
1stTrend ==========================> (1) ExitLong
1stCycle ==========================> (1) ExitLong

SHORT ENTRY: (any 1 is True)

TrendMode AND Bias_Short_SMA ====> (1 & 1) GoShort
CycleMode AND Reversal_Short ====> (1 & 1) GoShort

LONG EXIT: (any 1 is True)

TrendMode AND Bias_Long_SMA
CycleMode AND Reversal_Long
1stTrend ==========================> (1) ExitShort
1stCycle ==========================> (1) ExitShort

Using just "half" of this system work as well
(just Long Trades, or just Short Trades)

==========

NOTES on System Flexibility and Tweaking:

1) I'm constantly lookly to improve the 8 T/F Indicators,
espcially the Market_Mode Indicator

2) Including 1stTrend and 1stCycle Exits,
usually results in more trades with less downdraft.

3) Removing 1stTrend and 1stCycle Exits,
usually results in longer trades with more Gains.

4) Combining 1stTrend and 1stCycle with NOT (Bias_etc) indicators,
can makes them more precise. (ie. Exit trigger fires less)

5) It's helpful to have a TrendMOde Indicator that can
distinguish between UpTrendModes and DownTrendModes
(although the Bias Indicator's (3 & 4) recommended by Ehlers,
do a pretty good job of Predicting Direction,
depending on SMA window. Also I've that Parabolic SAR,
can work as a Bias Entry indicator as well.)

6) Momentum Reversal Indicator sometimes
work better when reversed (Short for Long)
depending on Window size used to create them,
Qtr, Half, Whole, Fixed; and how Reversal is measured.
(RMI can be a useful substitute here.)

7) If unsure how to get T or F (1 or 0) Indicators;
Hint I mostly use "Relational" category for these.

8) The Compound Rules can be made more complex
(like checking for 1 of 2 different Bias Indicators, using OR.)

This is just the basic Floorplan, but the design
can be customize to suit you Indicator preferences.

==========

Marecl, I hope that helps.
I've developed this TS strategy over many, many weeks,
of hard work, and am slightly hesitant to post it.

BUT in the spirit of information sharing and synergy
there you go ... gratis.

Marcel, por for vour,

can you give me a brief summary
on how you've been building and testing
0-lag indicators. Is TDNN the primary way
to verify 0-lag?

BTW How's trading going for you?
I've got "writer's block" on getting started, here.
No TS seems "good enough" so far.

stay curious

Heisenberg, Filters and Lag

Date :8/1/2005 9:52:54 AM Poster : Mark Simpson

So far we now know how to use neural nets successfully and we have a plan to
design a model. We have the exits figured, but we still need a 3 bar lag
at most or 0 bar lag ideally, indicator for entry to make a system that we would trade.
(We consider 4 bar lag entry and 0 bar at exit, a marginal profit case, so 3-0 is what we're aiming for, 0-0 is ideal, and you could argue is something you approach not
reach).

The question becomes, how do we achieve this, and to do that, the first stage is to
truely understand lag. Once we understand lag, we can figure out how to identify
zero lag indicators.

So, what is an regular indicator?

Most of the time, an indicator is really just a filter. E.G. SMA, RSI.
You feed data into a filter, and filtered data comes out of a filter. The filter
normally has some effect, i.e. it smoothes the data/removes noise, or
has some other predetermined effect so essentially its function(inputs)=output
where inputs is the input data plus lags of the inputs, and output is the filtered output.

For instance a Simple Moving Average (SMA) of close and of say 5 periods is:

(close + Lag(Close,1) + Lag(Close,2) + Lag(Close,3) + Lag(Close,4)) / 5

On a side note here, you can immediately see the similiarity to a TDNN mentioned
earlier. I.E. You could build a TDNN neural network to imitate practically any filter/indicator out there, afterall a TDNN is just the same, the only difference is it learns
the function instead of being given a mathematical expression for the function.
I leave this as an exercise to simulate say something like RSI with a TDNN.
When you create a TDNN to implement a function, you can also think of it as just
an indicator builder, i.e. you have the ability to create any indicator automatically and
the neural net constructs the best one for the job.

Filters are used regularly in electronics (long ago in analog, and commonly in digital these days), and what we're really doing here with our indicators in NST is
digital signal processing (DSP). I.E. We're using mathematical techniques
to implement our filters instead of analog techniques (electronic capacitors/resistors/inductors etc.)

If you consider price to be: signal+noise
Then filter(signal+noise)=signal

Now, when we start thinking of indicators as really filters, a few things start falling into
place.

First of all, we can use most DSP techniques in our models. We can also
use analog techniques but convert them to digital. This opens up a new realm
of indicators that we either don't see often, or aren't currently used at all in technical analysis. The issues in DSP are very similar to trading. Often they want to remove
noise, often reduce lag (or adjusting for phase), deal with quantization noise
(in our case quantization noise is 1 bar at any timeframe). Other areas that use
DSP heavily are astro physics and computer vision amongst many disciplines, and
many techniques can be borrowed from these areas.

Secondly, it's lag. Filters used for smoothing generally exhibit lag. It's a fact of
life and stems from the Heisenberg Uncertainty Principle (HUP) (all you Star Trek
fans, forget about transporters for a moment :-)). HUP can be applied to many
areas of physics, but how it applies to us is as follows.

The HUP states that you can't achieve both accuracy in the frequency and time
at the same time. One is the traded off against the other.

In terms of trading, frequency is the signal we're trying to get to without the noise, e.g.
the output of an SMA is the signal. Time is the location of the feature within time,
i.e. lag. 0 lag means we have accuracy in time, but then we don't have a signal (accuracy in frequency). 4 bars lag on an RSI means we have inaccuracy in Time
(we have lag), and are accurate in frequency (the RSI output).

You can have either/or frequency/time, but not both, and you can different levels or
trade offs inbetween.

An exercise to look at lag is to take the ZSineWave from earlier and feed it into an SMA.
Try:

1. Adjusting the frequency of the sine wave. You'll see the sine wave become attenuated at certain frequencies. Any pattern?

2. Looking at the lag. How much lag does the SMA add? How much phase is that
equivalent to?

3. Do other indicators have the same lag. What's the minimum lag you can get?

So essentially we have a fixed physical limit, and a big problem. We must get rid of
noise and get to the signal with zero lag. We need zero lag, because we need to model
the most recent bar on the chart. We already know that most indicators produce a minimum of 4 bars lag, and that won't do.

We know from earlier that with a cause and effect model, that we're modelling the effect
when we model price, so we're already late to the party. We don't want to be additionally late due to our indicators, so we need to approach zero lag.

I regard the HUP as a brick wall. Many people drive along a road and stop at the brick
wall. The brick wall is fixed and can't be moved. The majority of people look at the brick
wall, analyze it's mortar, try pushing on it, try figuring out techniques to dissolve the
brick wall. A JCB could knock down the brick wall, but we don't have a JCB
in this analogy :-). The reality is it's a brick wall and the brick wall is fixed, and a physical limitation. (and I've spent many hours trying to get through that brick wall
too)

So, now I've thoroughly depressed you, don't give up Technical Analysis yet.

The point is, forget about trying to push through the brick wall....

How about just going around it?

There are 4 classes/techniques I'm aware off (there maybe more, others who
know them, please contribute) that you can use to go around the wall. Some are relatively easy to use, some are more complex.

1. Deal with HUP.
If we need accuracy in the time domain, then we have to forego a signal and
acquire one via another means. I.E. Look for our answer by analyzing with
inaccuracy in the frequency domain and accuracy in time domain, or
some level inbetween. Wavelets for instance allow you that trade off. This approach
is commonly called Multi-Resolution analysis and tends to be complex.
It's an area my research is currently targetted in, but is something that I keep
close to me.

2. Probability.
James did a good job of introducing this topic. Essentially probability is
the likelyhood of something happening. The strongest use of probaility
based indicators tends to be using a contrarian view point. This is because
contrarian is zero lag. I.E. You take the opposite position while price is
going in a certain direction. The stronger the likelyhood, the
the more sure you can be of the result, but the less signals you get. You'll never be
100% accurate (and I don't believe any technique ever could be), but having 80%
confidence can be very good, and it allows you to tune your system to provide the
best.

3. Data Relationship
Some stocks can lead others, i.e. one stock moves, another might move a few
days later. Changes in the price of oil could have a knock on effect on retail.
Correlation between certain stocks could be high (correlation pairs), such that
when stocks become uncorrelated you can be reasonably sure
they will return to correlation and you can trade that move. These are
all "relationship" types, i.e. series1 leads series2. Because you know the
relationship between the 2 series, then you can predict series2 from series 1 and
you've removed lag. It can be tough to find these relationships and the obvious
ones are often traded away, but if you dig deep enough you can find them.

4. Model Cause
Forget trying to model the cause (price) and model the effect (the dynamics
of all traders working in different timeframes). Fundamentals also slot in this
category. (however bear in mind the data for these can be late). Again, it's
another area that can be frought with difficulty because of the amount of analysis
involved.

Out of 1,2,3,4: 1&4 are the hardest to achieve. and 2 is easier than 3, so unless you
have an indepth view of the market that makes 3 easier, it's quite often easiest to begin with the probability class type trades.

Re: Heisenberg, Filters and Lag

Date :8/1/2005 6:29:38 PM Poster : James Siebert

Mark

Thanks for the great summary of the system plan
the group has been working on.
It's given me a chance to catch up.

I particularly like the "Brick Wall" analogy for HUP,
and the "go around it" solution. (teleporting?)

Wavelets seem to be a good compromise
between the Freq & Time dimensions.
(the math is perplexing though)

here's the link that 1st helped me understand Wavelets:

http://users.rowan.edu/~polikar/WAVELETS/WTtutorial.html

I like your decomposition of SMA into
a trainable TDNN. Wow! great insight.
I'll have to explore this.

A few days ago I applied TDNN you described to
to Ehler's "0-Lag Smoothed Momentum" using the Q's
and got the best gain on the QQQQ I've ever seen:
(89% annual gain)

SimpsonLag_EhlersMomentumSMAqZ 010_A QQQQ TS2 89.cht

(File not included, because of DLLs)

as I read it, Ehler's Algorithm is:

EhlersMomentumSMAQtr:

VariableMomentum(VariableSMA(Close,QtrCycle),QtrCycle)

[MESA Book pg 50-51]

Thanks for the concept of TDNN,
I was not thinking in these terms before.

Mark you described a possible solution as:

> 3. Data Relationship
> Some stocks can lead others, i.e. one stock moves, another might move a few
> days later. Changes in the price of oil could have a knock on effect on retail.
> Correlation between certain stocks could be high (correlation pairs), such that

> all "relationship" types, i.e. series1 leads series2. Because you know the
> relationship between the 2 series, then you can predict series2 from series 1 and
> you've removed lag. It can be tough to find these relationships and the obvious
> ones are often traded away, but if you dig deep enough you can find them.

Here's a xls I put together a few months ago
which illustrates such a Leading Correlation

Euro_Yen_Dollar_LinXY.zip

Euro had a very strong leading
relation on the Dollar R^2 = 0.824
(SEE: 4th Chart down)

NOTE: this correlation was for 100 days in 1999

Used Pearson XY Correlation
to determine if a move in the Euro
resulted in a equivelent move in the Dollar.

The predictive strength of the Euro delta (X axis)
in fore-shadowing the opposite Dollar delta (Y axis)
as indicated
by the tightly grouped scatter points
around the diagonal Correlation Trend Line. (neg Slope)

The more widely dispersed the x-y points (Euro:Yen)
the less predictive influence a move in x
will have over a move y.

(Corelations > 0.7 indicate strong Probabilities
with 90% confidence levels or better)

ANOTHER possible Zero Lag Indicator may be "Cluster Analysis"
(the Charts at the bottom of Xls show such Clusters)

About 6 months I spent several weeks exploring this.

The math was messy, but the results were very good.
And the Clusters could be optimized as well,
(after a lot of perspiration setting up ranges).

"Cluster Analysis" is a well established Data Mining Technique.

Figuring out how to apply principles to
Time Series Market data was a trick, however.

The basic Idea is, that Events in an X-Y Scatter Chart
tend to group together into "similar Population" subsets,
(aka Clusters.)

Such Clusters tend to share similar properties. (ie. same signal)

If you've ever seen the Star Chart

that classifies Stars into Giant, Dwarfs, Normal, etc.
based on Luminosity vs Temperature,
then you've seen "Cluster Analysis" at work.
(SEE Link: for Hertzsprung-Russell diagram)

http://www.clustan.com/clustering_v_decision_trees.html
(Site has a good description of "Cluster Analysis")

The idea is to isolate the ranges of the properties
which identify "similar Events" (or types of Stars)

I found that by normalizing X Data Series
and Y Data Series, using Z-Scores (of course)

then by using simple Circles, centered at (+-1SD),(+-1SD)
I would have a mechanism for
measuring "similar Price Events" (x-y Events)

(and a way to take advantage of any Leading Correlations,
Like Increase in Euro ==> Decrease in Dollar)

By counting Events which "hit" within the Circle
and optimizing what the Circle radius should be (in units of SD),
using NS traning.

Then Tradable Triggers and identifiable signals,
can be built into a concise system of rules.

NOTE: I was able to simulate the Cluster Boundary
using Pythagorus Distance formula, centered at (+-1SD),(+-1SD)

Given any Event x and y how far is (x,y) from center C?
Is that distance less than the Circle Radius
(at Cluster1 (+1SD,+1SD))?

if so, then tally another Cluster1 Event
and so on. this can Result in early identification
of trend changes, counter-trend strength etc.

later

It does tend to be ugly. One of the main issues with wavelets is what you
pick as the mother wavelet. However the mother wavelet still starts/ends at
0 which means that you get End Point Distortion and HUP is the limit. The
EPD essentially varies according to the scale of the wavelet.

Also, because it's analyzed in terms of a mother wavelet, then the result
is in terms of a mother wavelet which can be difficult to use.

>Here's a xls I put together a few months ago

You're a wiz with excel, and the analysis is sound. Try it out in NST,
you'll find NN's do quite well with leading correlation type models. If you don't
want to use clustering, there's a clustering add-on that will likely do the trick too.
Nice work.

Mark

Thanks again for looking at the correlation xls
and taking time to comment.

Yes, you might say, that I "excel" with Excel.
(chuckle, sorry)

Indeed I find Excel to be a very powerful tool for
brainstorming, prototyping, and visualizing concepts.
There are times I wish NST was more like Excel,
but I imagine there are many very good reasons why it isn't.

A WYSIWYG chart-like view of before/after NN
Solution Landscapes would be VERY cool, in NST,
but that's probably expecting too much, given the limits of 3-D Graphics.
However, being able to "post back" optimized parameters calcs,
as new Indicator SubCharts, right from the Results Tab,
is probably very do-able. (this is a task, that I always want, but rarely do)

I frequently build my ideas in Excel first,
to see if the idea has any merit, and what the formula should be,
and then rebuild the calcs in NS to validate the theory.

Re: correlation analysis xls.

I was very amazed when I saw
the Euro was negatively correlated the Dollar,
to such a significant degree;
It was predictive even 3 days in advance
(see the Charts down and to the right, and
check Chart Titles, for Days Lead.)

I did at the time, try to do something with this in NS,
but jumped straight to TS (skipping NN)
and was primarily focused on
using X:Y Correlation Rsq Scores (>= 0.7)
as a triggering threshold for Trade Entries.

Now I think I might of been off track with this approach.
I couldn't get consistent results, at the time,
with just the Correl Peaks above a certain threshold.
(frequently the Rsq drops below 0.7 on a day to day basis,
(not sure why?)
and by itself Rsq tells you nothing about
the direction or timeliness of the move.)

I should look at this some more,
especially since I learned that intermarket Correlations
can be a source "untapped" Zero-Lag trading systems. :)

Thanks for the tip about Cluster Analysis Add-on;
I will need to find out more this tool, as well.

Re: Heisenberg, Filters and Lag

Date :8/7/2005 6:52:10 PM Poster : Marcel

Mark et al,

Sorry for having been quiet for a few days... had to digest HUP!

Although I think to have a good understanding of HUP from an academic perspective, I needed in-depth practical experimentation (something Heisenberg didn't like at all) and proof that the principle applies. Maybe it's because I've spent months and months trying to find inexistent solutions, but facing and accepting the evidence was quite struggling this time. I didn't want to give up that easily in front of the "brick wall" and I had to pay my own tribute.

For anyone who stands in front of the wall wondering what to do next, I can only advise to experiment as much as possible – reading or listening to others won't probably provide the necessary confidence that you learned your lesson. For me, I've taken simplified time series like the modulated sine curves and I've started to test one indicator after another, until I learned that there is no conventional way one can gain high probability about future price direction (buy/sell signal) without introducing this killing lag of 3-4 days. If you don't believe in it yet, take all your unsatisfactory models and lead the inputs by 1 or 2 days – you will be surprised!

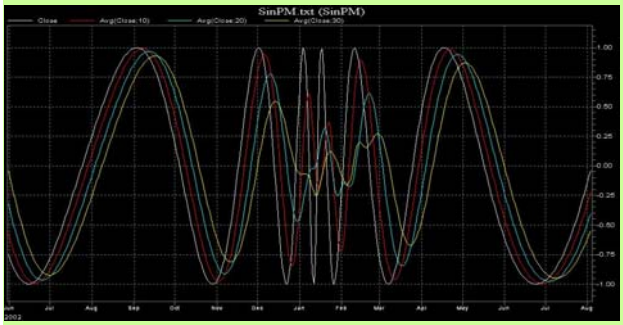
Despite my own HUP lesson, I still questione myself: What do the hundreds of people out there that claim to be successful with NN really do? Next to all those that give up before ever having had one single working model, I assume that the majority of them are sitting there by the brick wall, some of them fighting hard to get through. And yet some of them claim to be successful... Are their models only lucky shots? Or did they find a hole in the wall? If I read the "interviews with Real Traders" on the NeuroShell.com site, I can hardly believe they have all gone around the wall...

What's your opinion on this?

Now a few replies to the original article:

> An exercise to look at lag is to take the ZSineWave from earlier and feed it into
> an SMA.
> Try:
>
> 1. Adjusting the frequency of the sine wave. You'll see the sine wave
> become attenuated at certain frequencies. Any pattern?
>
> 2. Looking at the lag. How much lag does the SMA add? How much
> phase is that equivalent to?
>
>3. Do other indicators have the same lag. What's the minimum lag you
> can get?

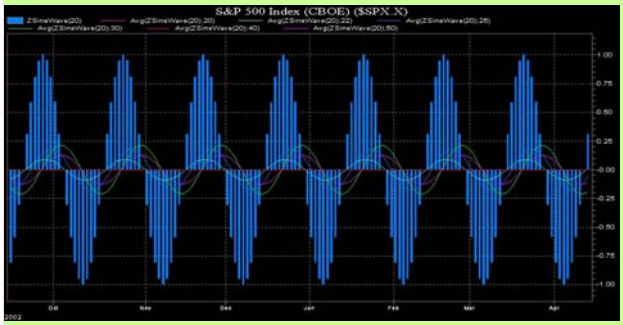
The above can be partially demonstrated by using one of the charts I posted here in a previous article (http://www.ward.net/cgi-bin/Forum/Forum_Article.asp?a=2591). By adding a 10, 20 and 30 days SMA to the phase (or frequency) modulated sine wave, we get the following picture:



Two considerations become evident:
a) The amplitude of the SMA is a function of sine wave frequency
higher frequency >> smaller SMA amplitude
b) The amplitude of the SMA is a function of averaged period
longer period averaged >> smaller SMA amplitude

What is less evident but trained eyes will have observed, is that at high frequency the SMAs behave strangely, introducing something that looks like resonance frequencies (see yellow line at the center of the picture). It seems as if there are different phenomenons going on when the averaged period of the SMA is greater than the sine wave frequency.

Let's look at another chart, a ZsineWave(20) plus SMAs of 20, 22, 25, 30, 40 and 50 days:



The observations are:
a) All the SMAs are much smaller in amplitude, but reflect the same frequency as the underlying sine wave
b) The 20 and 40 SMAs are not visible, being a multiple of the 20 bars underlying sine wave, they become zero
c) The four remaining SMAs (22, 25, 30 and 50) have:
c1) Different amplitudes, the closer they are to the base period of 20, the smaller they get – till zero (see b)); analogically, the 30 days SMA is the highest in the above example
c2) But more interesting they are dephased from the underlying sine wave, does that mean that the conventional lagging theory gets messed up? Look at the SMA(22) for instance, it's exactly in phase with the underlying sine wave. Where has the lag gone?

(You will think now: "If only stock prices charts would look like sine waves...")

Well, let's look at the lag then. Plot SMAs of 4, 6, 8, 10 etc. and you will see that the lag is roughly 0.5 * averaged period of the SMA. The more the averaged period gets closer to the sine wave period, the more their amplitude tends to zero – when greater, they resurge from zero with an inverted shape.

So, sorry to disappoint, but the SMA(22) above is nothing else than an inverted sine wave – unfortunately lagged by 11 bars, therefore useless for our objective of predicting!

How much phase does lag equate to for a SMA? If base period = 20 and lag = 2, Phase is 360°2/20 = 36 degrees = Pi/5 radians. It follows (lc = lag coefficient):
Phase (deg) = lc * 360 * Averaged period / Base period
Phase (rad) = lc * 2Pi * Averaged period / Base period

Do all indicators display the same lag or lag coefficient lc?

Not really (empiric estimation averages based on sine wave - non representative):
- SMA = 0.45
- EMA = 0.25
- AMA = 0.30
- LinWgtAvg = 0.29
- Jurik MA = 0.28

I know the next one is theoretically wrong, but for sine waves the turning points are marked by the RSI with no lag. The problem is the curve shape, the RSI does not know that a turning point is about to happen, apart from extreme values 20 <> 80 = higher probability. It has however higher chance to be used for predictions (HUP at work). Jurik RSX is slightly lagged, but its curve reacts quicker to changes in slope or frequency.
- RSI = 0
- Jurik RSX = 0.1–0.3

Other conventional indicators fall either in the category of the moving averages with a lag coefficient of around 0.25-0.5 (e.g. Efficiency, Standard Deviations, Z-Score), or have a zero - or close to zero - lag coefficient (e.g. Simple Stochastics, Regressions) while introducing disadvantages as noted under RSI above, or simply can not be measured with sine waves (e.g. Momentum, Velocity, Acceleration, B-Bands).

I hope the above helps to move a step forward.
Best Regards,
Marcel

You're wize in your approach and I can see now that you've truely got it (and pretty

fast too).

It took me about 1 month to formulate the concepts in my head and probably around a year to be comfortable with it and identify solutions (the 4 methods I discussed in previous emails). There was a lot of double questioning of myself going on in that time. Essentially it's a completely new way of thinking about things, and gives you the ability to look at any model and say, "Yes this could work", or "No this definately does not work". Then you can just concentrate on building the things that do work.

>Despite my own HUP lesson, I still questions myself: What do the hundreds >of people out there that claim to be successful with NN really do? Next to >all those that give up before ever having had one single working model, I >assume that the majority of them are sitting there by the brick wall, some >of them fighting hard to get through. If I read the "Interviews with Real Traders" on the NeuroShell.com >site, I can hardly believe they have all gone around the wall...

I think you'll find that many of the "Real Traders" on Neuroshell.com have actually gone around the wall, judging by limited information you can glean from their vague (of course they wish to protect their Intellectual Property) descriptions of their system. Sometimes people accidentally find their way around the wall without realizing the wall is there, but they've been testing some methods/ideas extensively and noticed one of them works, and stick with it and develop it. These tend to be probability based, or based on some data series leading another. Statisticians/Mathematicians who put their skills to trading also tend to start off with probability based methods because of their familiarity with it and the methods, so are generally successful earlier on.

The other point is all these indicators don't seem to be much use, can be very useful if you feed a truely leading data series to them.

The other thing that goes on is curve fitting. Some people convince themselves that a conventional approach works by misusing the tools they have.

For instance (and we'll demonstrate this later in the curve fitting section), you can take any indicator (lets say an RSI for example), and genetically optimize to fit say 4 or 5 trades, and it will work very well. Now if you take say 10 indicators and put them into the model, you can now build a model validated on say 100 trades, and get good results with optimization. However it either works for a little while then stops working and they have to re-optimize, or it never works in real time.

Essentially you can piecewise linear fit a curve, and that process people sometime hit upon, but often don't understand why. That is one technique to make a conventional model work. Personally I have it on my "risky" list, purely because it's more difficult to produce on going results than with other techniques for getting around HUP. We'll go into that more on the section about curve fitting.

So overall, it's not all bad news. Most people are stuck at the brick wall, and we have to do a little more leg work to get around it. The people at the brick wall often think we're crazy, because the brick wall is what most people do, and masses must always be right.

However ironically, we need to model the masses and to do this we need to be aware of what they're doing to get ahead (leading) of the masses.

Also, NST is an extremely powerful toolkit. Used in the correct way, these tools are dynamite. In my opinion it's the best toolkit out there. Practically any indicator you need has already been coded (even new ones in TASC), and you have serious neural networks and genetic optimization. However, like any extensive toolkit, you have to be careful that you stick your head up above it all and have a look around. The point being that it is way too easy to sit on the ground amongst your array of tools, trying to figure if this new tool you're learning is the single answer to the issue. You couldn't build a chair with just a hammer, and also if you need a clamp to hold the chair whilst building, only one clamp out of the 40 you have may work for the task in hand.

I'll reply to the rest when Ward have attached the images (probably Monday).

Re: Heisenberg, Filters and Lag

Date :8/8/2005 9:27:26 AM Poster : chris wong

i got over the brick wall marcel as soon as i realized the brick wall was only in my head. i used to think i had to find the keys to some magic kingdom where i'd discover the holy grail. then i came to understand that you have to see the glass as half full, not half empty. you have many somewhat good systems around you, stochastics, crossovers, simple neural nets, ideas on this forum, etc. together they are more than a full glass. the concept of diversified portfolios has been around for decades, why not diversify systems by finding ways to make them work together or confirm one another, as well as apply them to a diversity of stocks? giving credit where it is due, i got this idea from the ai college, but i don't think mr. ward invented the concept, because it is also old. read example 6 to get going on the concept, but i found things don't need to be nearly as complex as example 6. once you realize there is no brick wall you realize making good systems is not rocket science - e pluribus unum.

On 8/7/2005 6:52:10 PM Marcel wrote:
Mark et al,

Sorry for having been quiet for a few days... had to digest HUP!

Although I think to have a good understanding of HUP from an academic perspective, I needed in-depth practical experimentation (something Heisenberg didn't like at all) and proof that the principle applies. Maybe it's because I've spent months and months trying to find inexistent solutions, but facing and accepting the evidence was quite struggling this time. I didn't want to give up that easily in front of the "brick wall" and I had to pay my own tribute.

For anyone who stands in front of the wall wondering what to do next, I can only advise to experiment as much as possible – reading or listening to others won't probably provide the necessary confidence that you learned your lesson. For me, I've taken simplified time series like the modulated sine curves and I've started to test one indicator after another, until I learned that there is no conventional way one can gain high probability about future price direction (buy/sell signal) without introducing this killing lag of 3-4 days. If you don't believe in it yet, take all your unsatisfactory models and lead the inputs by 1 or 2 days – you will be surprised!

Despite my own HUP lesson, I still questions myself: What do the hundreds of people out there that claim to be successful with NN really do? Next to all those that give up before ever having had one single working model, I assume that the majority of them are sitting there by the brick wall, some of them fighting hard to get through. And yet some of them claim to be successful... Are their models only lucky shots? Or did they find a hole in the wall? If I read the "Interviews with Real Traders" on the NeuroShell.com site, I can hardly believe they have all gone around the wall...

What's your opinion on this?

Now a few replies to the original article:

> become attenuated at certain frequencies. Any pattern?
>
> 2. Looking at the lag. How much lag does the SMA add? How much
> phase is that equivalent to?
>
>3. Do other indicators have the same lag. What's the minimum lag you
> can get?

The above can be partially demonstrated by using one of the charts I posted here in a previous article (http://www.ward.net/cgi-bin/Forum/Forum_Article.asp?a=2591). By adding a 10, 20 and 30 days SMA to the phase (or frequency) modulated sine wave, we get the following picture:

SinPMplusSMA.jpg

Two considerations become evident:
a) The amplitude of the SMA is a function of sine wave frequency
higher frequency >> smaller SMA amplitude
b) The amplitude of the SMA is a function of averaged period
longer period averaged >> smaller SMA amplitude

What is less evident but trained eyes will have observed, is that at high frequency the SMAs behave strangely, introducing something that looks like resonance frequencies (see yellow line at the center of the picture). It seems as if there are different phenomenons going on when the averaged period of the SMA is greater than the sine wave frequency.

Let's look at another chart, a ZsineWave(20) plus SMAs of 20, 22, 25, 30, 40 and 50 days:

ZSinPlusSMA.jpg

The observations are:
a) All the SMAs are much smaller in amplitude, but reflect the same frequency as the underlying sine wave
b) The 20 and 40 SMAs are not visible, being a multiple of the 20 bars underlying sine wave, they become zero
c) The four remaining SMAs (22, 25, 30 and 50) have:
c1) Different amplitudes, the closer they are to the base period of 20, the smaller they get – till zero (see b)); analogically, the 30 days SMA is the highest in the above example
c2) But more interesting they are dephased from the underlying sine wave, does that mean that the conventional lagging theory gets messed up? Look at the SMA(22) for instance, it's exactly in phase with the underlying sine wave. Where has the lag gone?

(You will think now: "If only stock prices charts would look like sine waves...")

Well, let's look at the lag then. Plot SMAs of 4, 6, 8, 10 etc. and you will see that the lag is roughly 0.5 * averaged period of the SMA. The more the averaged period gets closer to the sine wave period, the more their amplitude tends to zero – when greater, they resurge from zero with an inverted shape.

So, sorry to disappoint, but the SMA(22) above is nothing else than an inverted sine wave – unfortunately lagged by 11 bars, therefore useless for our objective of predicting!

How much phase does lag equate to for a SMA? If base period = 20 and lag = 2, Phase is 360*2/20 = 36 degrees = Pi/5 radians. It follows (lc = lag coefficient):
Phase (deg) = lc * 360 * Averaged period / Base period
Phase (rad) = lc * 2PI * Averaged period / Base period

Do all indicators display the same lag or lag coefficient lc?

Not really (empiric estimation averages based on sine wave - non representative):
- SMA = 0.45
- EMA = 0.25
- AMA = 0.30
- LinWgtAvg = 0.29
- Jurik MA = 0.28

I know the next one is theoretically wrong, but for sine waves the turning points are marked by the RSI with no lag. The problem is the curve shape, the RSI does not know that a turning point is about to happen, apart from extreme values 20 <> 80 = higher probability. It has however higher chance to be used for predictions (HUP at work). Jurik RSX is slightly lagged, but its curve reacts quicker to changes in slope or frequency.
- RSI = 0
- Jurik RSX = 0.1–0.3

Other conventional indicators fall either in the category of the moving averages with a lag coefficient of around 0.25-0.5 (e.g. Efficiency, Standard Deviations, Z-Score), or have a zero - or close to zero - lag coefficient (e.g. Simple Stochastics, Regressions) while introducing disadvantages as noted under RSI above, or simply can not be measured with sine waves (e.g. Momentum, Velocity, Acceleration, B-Bands).

I hope the above helps to move a step forward.
Best Regards,
Marcel

Chris,

You are addressing an essential psychological aspect, the half full / half empty glass. Setting realistic expectations, managing drawbacks or cut losses are some of the fundamentals all of us have to deal with – while building our models, testing them and finally when they are implemented. I see the "holy grail" to be a nice dream at the very beginning, quickly moving into background when frustration and deception inevitably arises. Despite being replaced by other targets like technical challenges, personal education or researcher instincts, I believe it has to remain there as a nice dream, giving us direction and underlying motivation.

I also think there is not one single "brick wall", all of us have our own one(s). Through discussion we can find similarities, and together we can quicker find ways how to circumvent or overcome them. In these past threads we have been discussing the HUP (Heisenberg Uncertainty Principle) "brick wall", which is a very important eyes opener. I have a number of models implemented on the basis of example 6 which I trade, but for reasons stated previously I don't consider them to be behind this "brick wall". I encourage you to go through all the articles posted here in the past 6 weeks, and if you think we are missing out something, please enlighten us.

Thanks, Marcel

Heisenberg, Filters and Lag: Lag Exercises

Date :8/1/2005 10:31:24 AM Poster : Mark Simpson

Here's a few exercises that help figure out if an indicator is zero lag or lagging.

1. Z-Score. James has already mentioned that Z-Score is zero lag. But
if it has a Simple Moving Average in it's calculation, and a Simple Moving
Average has lag, then why is Z-Score zero lag?

2. Is RSI lagging or zero-lag and why?

3. If you were to sell short on RSI>80 would that be zero-lag?

4. Are bollinger bands zero lag?

5. If we smoothed a Z-Score, would that be zero lag?

6. If oil lead retail, and we did a RSI of oil and looked for extreme values of RSI
would that be zero lag?

7. If we have an indicator Lag(SMA(Close,5),3) is that zero-lag?

8. If we created a crossover indicator,
Crossover (price, Lag(SMA(Close,5),3)) would that be zero-lag?

9. If we were to train a neural net to learn RSI, would that neural net be zero-lag?

10. If we had an indicator which provided the probability of price being a peak
or valley, and a peak was Lag(Close,1)>Lag(Close,2) AND Close
And here's some tougher ones:

a) If we did an Fast Fourier Transform of price, would we have zero-lag?

b) Under what circumstances would a crossover be zero lag?

c) When can a zero-lag indicator be considered leading?

d) What technique do you use to make a lagging indicator zero-lagged?

e) How many neurons in your average ant (you've actually read this far? :-))

Re: Heisenberg, Filters and Lag: Lag Exercises

Date :8/1/2005 8:56:57 PM Poster : Steve Eberbach

I have succesfully used Z-score when using GRNNs which demand better normalizing.
I convert most everything to Z-scores.

What is quite interesting is to use "future" Z-scores (as a target), whereby the daily fluctuation is zero lag, by virtue of using "today-unsmoothed" compared in relation to a future range defined by the standard deviation of future movement over an interval.. So the smoothed part is only a normalization, not entirely based on daily fluctuation. This is a useful target, I have found. Partly zero lag, partly leading. An excercise to bend your brain: Is a Z-score comparing 5-day smoothed close with future 5-day standard deviation of open, high, low, close from 5 day future smoothed mean zero lag? Negative lag?

Re: Heisenberg, Filters and Lag: Lag Exercises

Date :8/1/2005 11:36:27 PM Poster : James Siebert

Here goes nothing, my educated guesses:

1. Z-Score. James has already mentioned that Z-Score is zero lag. But
if it has a Simple Moving Average in it's calculation, and a Simple Moving
Average has lag, then why is Z-Score zero lag?

Z-Score rates the likeliness of an Event
(how unusual is it).
Z-Score do not tell you where tomorrow's price is headed,
like a SMA(5) would for 5 days ago.

Flip a coin 5 times in row, with all Heads,
Z-Score(30) would be somewhere around 3 or more,
but the next flip could easily be heads again,
however probabilities says that the "mean will return"
should lead you to bet on Tails.

2. Is RSI lagging or zero-lag and why?

Lagging, RSI calculation keeps averaging
and carrying forward yesterdays values,
then adding todays value to the mix.

The indicator has a "memory" of the past
and today's up or down move, attempts to
adjust that memory in today's direction,
if only slightly.

3. If you were to sell short on RSI>80 would that be zero-lag?

I would guess Yes, since RSI "can't stay oversold forever"
in other words it's likely to correct
and revert to the mean (50) soon.
(caveat, break out trends, can postpone the correction)

4. Are bollinger bands zero lag?

I think Yes, since they are rely on Standard Deviation
and the "probability" of Prices returning
from the outer Bands back to the Center Channel (0 SD),
is very good.

5. If we smoothed a Z-Score, would that be zero lag?

No, averaging the Z-Score, would cause the smoothed line
to follow the Z-Score direction but only "after the fact"
ie lagged.

6. If oil lead retail, and we did a RSI of oil and looked for extreme values of RSI
would that be zero lag?

maybe, if we are assuming the RSI correction from extremes
would also occur in Retail RSI, shortly afterwards.

Would be better to you use Pearson X-Y Correlation
between Oil and Retail, and determine which indicators
are related. Maybe RSI is NOT the determining factor (X)
preceding the Retail indicator (Y),
but maybe it's the Oil Momentum Indicator
that leads Retail instead

7. If we have an indicator Lag(SMA(Close,5),3) is that zero-lag?

NO, 5+3 days of Lag = 8 days of Lag.

Without the trick of 90 degree Phase-shift (QtrCycle Lag)
Usually Lag + Lag cannot not be converted to Lead.

Qtr trick is due to the Identity of Sines and Cosines

y(t) = A Cos(wt + Theta) = A Sin(wt + Theta + (PI/2))

Where Theta is Phase Angle change
and (PI/2) is the QtrCycle Phase shift (90 degrees)
and wt is the angular frequency (rate of the cycle change)

8. If we created a crossover indicator,
Crossover (price, Lag(SMA(Close,5),3)) would that be zero-lag?

Possibly Yes, depending on how it is used.
Once a price crosses a Average line,
it tends to stay there for a while,
until the cycle progresses or
the trend corrects.

I use
CrossOver(Price, SMA(Price)) as a "Long entry bias"
CrossBelow(Price, SMA(Price)) as a "Short entry bias"
in conjuction with my MarketMode Indicator (for Trend)

If "Trend_Mode" goes to True,
I look at the "SMA Bias" to determine if
Entry should be either Long or Short.

"A Price above Average tends to stay above Average"
and v.v.

9. If we were to train a neural net to learn RSI, would that neural net be zero-lag?

Don't know, maybe 0-Lag?
It could be that the Net
learned to anticipate the "Return to Mean" behaviour,
as it approximated/learned the "profitable" solution spaces.

10. If we had an indicator which provided the probability of price being a peak
or valley, and a peak was Lag(Close,1)>Lag(Close,2) AND Close

This indicator would have 1-day lag, since the middle value
out of the 3, is the one being estimated, as the peak.

And here's some tougher ones:

a) If we did an Fast Fourier Transform of price, would we have zero-lag?

No, we'd have the Frequency Compenents in the data,
how often it repeats, but not when it will.
(units of cycles, not days)

b) Under what circumstances would a crossover be zero lag?

when it's used as contrarian bet,
as when the crossover of an extreme threshold
indcates a likely return to the mean.

c) When can a zero-lag indicator be considered leading?

when it's in Cycle_Mode and a Phase-shift is applied
to project future Cycle stages into "leading info" now (see answer 7)

d) What technique do you use to make a lagging indicator zero-lagged?

1) pass it thru a Z-Score.

2) pass it thru Bollinger Band calcs.

3) find a Leading Correlated Indicator in another market
which precedes the lagging indicator of interest.

4) Analyze it with wavelets,
for both "some" Time and "some" Frequency data simulataneously.
Wavelet minimize the HUP tradeoff
between the Timeliness and the Accuracy of Signal data.

5) Find ways to minimize or reduce the Noise like (H+L+O+C)/4
or maximize the Signal (like Momentum)

6) decompose the Lagging Indicator into component parts,
add those to a Neural Net, so the context of the Lags can be "learned"
and bought forward into the present.

7) 90 degree Phase-shift (Quarter Cycle shift)
if market is in Cycle Mode

likely more ??

e) How many neurons in your average ant (you've actually read this far? :-))

100 per ant x 100,000 per colony x goal-seeking behavoir patterns
= very intelligent action, for a dumb insect. ;)

>however probabilities says that the "mean will return"
>should lead you to bet on Tails.
Correct. The way I see it is a little different.
ZScore = (X - SMA(X,N)) / Standard Deviation(X,N)

Where X is price and N is the number of periods. Essentially (because N is
large and not 1), is:

ZScore = (X - Smoothed) / Smoothed
I.E. SMA and Standard Deviation are both indicators which are a calculation on
many seperate values, i.e. lag is introduced.

However X is zero lag (assuming you're using price).

So we really have:

ZScore = (0 Lag - P lag) / P Lag
Where P is some amount of lag between say 0.5N and 0.25N (from earlier post).

Now from a maths point of view (and James being a statistician can likely put it
together more formally than I can), the 0 lag component is the
major component that effects the series, because P Lag changes slowly throughout time.

Therefore because it's the major component it effects the result more, therefore ZScore
itself is zero lag.

>2. Is RSI lagging or zero-lag and why?

>Lagging, RSI calculation keeps averaging
>and carrying forward yesterdays values,
>then adding todays value to the mix.

>The indicator has a "memory" of the past

Correct.

>3. If you were to sell short on RSI>80 would that be zero-lag?

>I would guess Yes, since RSI "can't stay oversold forever"
>in other words it's likely to correct
>and revert to the mean (50) soon.
>(caveat, break out trends, can postpone the correction)
That's an interesting way of thinking about it, i.e. using a lagging indicator in a contrarian
use to make it leading.

What I've found personally is that using something like Z-Score and then using contrarian is better because you have a zero lag (arguably leading) followed by zero-lag
contrarian, rather than (with RSI) lag, plus then a zero-lag technique. I.E. RSI
even when used in a leading sense, still contains a chunk of lag in it.

>4. Are bollinger bands zero lag?

>I think Yes, since they are rely on Standard Deviation
>and the "probability" of Prices returning
>from the outer Bands back to the Center Channel (0 SD),
>is very good.
I'd say yes and no. Because BBands are:

SMA(X,N) +- (mult * StandardDeviation(X,N))

Mult is a constant. And SMA/StandardDeviation are not zero lag. That's the No.

The yes would be due to the same reasons as the last question. I.E. Contrarian use at
a certain level, i.e. a BBand breakout, but again it would have the same issue with lag.

>5. If we smoothed a Z-Score, would that be zero lag?

>No, averaging the Z-Score, would cause the smoothed line
>to follow the Z-Score direction but only "after the fact"
>ie lagged.
Correct.

>6. If oil lead retail, and we did a RSI of oil and looked for extreme values of RSI
>would that be zero lag?

>maybe, if we are assuming the RSI correction from extremes
>would also occur in Retail RSI, shortly afterwards.
Correct. I.E. The RSI of oil, (which has an amount of lag, lets say for this example 4
bars), precedes the move in Retail by at least 4 bars to be zero lag.

>Would be better to you use Pearson X:Y Correlation
>between Oil and Retail, and determine which indicators
>are related. Maybe RSI is NOT the determining factor (X)
>preceding the Retail indicator (Y).
>but maybe it's the Oil Momentum Indicator
>that leads Retail instead
Correct. Incidently another thing that is worthy looking at is serial correlation within
a stock itself.

>7. If we have an indicator Lag(SMA(Close,5),3) is that zero-lag?

>NO, 5+3 days of Lag = 8 days of Lag.
Yes and no. If you take the indicator itself, the answer is a plain no.
However it can be used as an effective trend exit signal. It's commonly called
DMA (Displaced Moving Average) and seems a weird concept at first.
Essentially you're displacing a 5 day moving average, and by doing that it
gets you the responsiveness of a 5 day moving average, but can be used as a trend

termination (or entry) signal because it's been displaced enough in time
to move it out of the way of being whipsawed. Plot it on a chart and you see it can
work for when price>DMA (or conversely).

>Without the trick of 90 degree Phase-shift (QtrCycle Lag)
>Usually Lag + Lag cannot not be converted to Lead.

>Qtr trick is due to the Identity of Sines and Cosines

>y(t) = A Cos(wt + Theta) = A Sin(wt + Theta + (PI/2))

>Where Theta is Phase Angle change
>and (PI/2) is the QtrCycle Phase shift (90 degrees)
>and wt is the angular frequency (rate of the cycle change)
Advancing phase will work, however you have to be careful to make sure that you
have a good analysis of phase/frequency in the first place.

>8. If we created a crossover indicator,
>Crossover (price, Lag(SMA(Close,5),3)) would that be zero-lag?

>Possibly Yes, depending on how it is used.
>Once a price crosses a Average line,

>I look at the "SMA Bias" to determine if
>Entry should be either Long or Short.

>"A Price above Average tends to stay above Average"
>and v.v.
I accidentally answered that one in 7. (and your correct) :-)

>9. If we were to train a neural net to learn RSI, would that neural net be zero-lag?

>Don't know, maybe 0-Lag?
>It could be that the Net
>learned to anticipate the "Return to Mean" behaviour,
>as it approximated/learned the "profitable" solution spaces.
If you train a neural net to learn RSI, then it will have as much lag as RSI. However,
you could always try to teach it Lead(RSI,4), but you're going to come up against HUP
and the neural net will become very poor at predicting.

>10. If we had an indicator which provided the probability of price being a peak
>or valley, and a peak was Lag(Close,1)>Lag(Close,2) AND Close

>This indicator would have 1-day lag, since the middle value
>out of the 3, is the one being estimated, as the peak.
Correct.

>And here's some tougher ones:

>a) If we did an Fast Fourier Transform of price, would we have zero-lag?

>No, we'd have the Frequency Compenents in the data,
>how often it repeats, but not when it will.
>(units of cycles, not days)
Correct. Also (and this one is important if you're ever doing frequency analysis using FFT's for trading), an FFT has to start and end at zero, otherwise you get significant
noise throughout the spectrum. Because of this a hanning window (or other window)
that makes the data end (and start) at zero is commonly used. Unfortunately the
area you want to model is the end point, i.e. the most recent bar. So you've
just wiped out any possible chance of doing any reasonable analysis because you've
introduced significant End Point Distortion (EPD) from the FFT requirements themselves.

>b) Under what circumstances would a crossover be zero lag?

>when it's used as contrarian bet,
>as when the crossover of an extreme threshold
>indcates a likely return to the mean.
Plus, when you're crossing over a zero lag indicator.

>c) When can a zero-lag indicator be considered leading?

>when it's in Cycle_Mode and a Phase-shift is applied
>to project future Cycle stages into "leading info" now (see answer 7)
Good thinking and right, but HUP is the gotcha.

>d) What technique do you use to make a lagging indicator zero-lagged?

>1) pass it thru a Z-Score.
That would still be lagged.

>2) pass it thru Bollinger Band calcs.
Still Lagged

>3) find a Leading Correlated Indicator in another market
>which precedes the lagging indicator of interest.
Correct.

>4) Analyze it with wavelets,
>for both "some" Time and "some" Frequency data simulataneously.
>Wavelet minimize the HUP tradeoff
>between the Timeliness and the Accuracy of Signal data.
Minor lag, but you get some distortion that has to be handled from
the process itself.

>5) Find ways to minimize or reduce the Noise like (H+L+O+C)/4
>or maximize the Signal (like Momentum)
Momentum introduces lag however, as you normally need longer momentums
to produce a usable signal.

>6) decompose the Lagging Indicator into component parts,
>add those to a Neural Net, so the context of the Lags can be "learned"
>and bought forward into the present.
Good thinking.

>7) 90 degree Phase-shift (Quarter Cycle shift)
>if market is in Cycle Mode
A lot of the cycle mode/trending concept tends to come from the idea
that things are consistant. I believe the issue here is are understanding of time
(which I'll go into in later posts).

>likely more ??

>e) How many neurons in your average ant (you've actually read this far? :-))

>100 per ant x 100,000 per colony x goal-seeking behavoir patterns
>= very intelligent action, for a dumb insect. ;)
I checked this one out, just out of interest. A Cataglyphis ant has about 960,000 neurons which is pretty impressive, and I presume it varies a lot depending on the
ant in question.

Incidently in case you're wondering why we can't build an ant brain tomorrow. The
issue is processing time. Neurons in living matter are relatively slow, but can
all fire as a network as once, i.e. they all like individual basic processors that can
all fire in parallel. On a computer you have a serial computer processing a parallel
concept, so each neuron has to be processed in turn. Though a computer neuron is much faster than the biological one, the serial processing makes any
network of neurons of reasonable size a lot slower. And of course parallel
computing isn't really up to the task either at this stage. Maybe in the future...

> the 0 lag component is the
> major component that effects the series,
> because P Lag changes slowly throughout time.

> Therefore because it's the major component
> it effects the result more,
> therefore ZScore itself is zero lag.

So Why is Z-Score 0-lag?

If you use N = 30

(which I usually do with Z-Score
since most statisticians consider
30 the minimum Sample Size,
with a "good" degree of accuracy, around 90% Confidence)

and assume P lag is one half the N window:

P Lag = 0.5N = 0.5 * 30 = 15 days Lag

then

ZScore = (0 Lag - P lag) / P Lag

becomes

ZScore = (0 Days Lag - 15 Days lag) / 15 Days Lag

= -15 / 15

= -1

Not sure was this tells you?? (a measure of probablity?)

I always thought Z-Scores were 0-lag
since they were measuring/predicting
by using "probability",

and classic probability has "no memory" of the past
(non-conditional Probability, with replacement).

or in layman terms:
"each coin flip is independent of the last one"

A ZScore of +3 today, does not prevent me
from seeing a -3 Score tomorrow.

This type of move is not so easy in
a Lagging Indicator, like SMA:

There is a "certain interia" that must be reversed
within the SMA data series, for such a move.
One day's Value cannot "move the curve" so quickly.
There is a "degree of continuity" that must
be maintained in the Indicator from Day to Day.
(SMA is always "slow to react")

In the ZScore, each Daily Score is "discontinuous"
from the last one. Z-Scores can vary "all over the map",
although they usually don't.

What gives the ZScore its usefulness is its built-in "context".
A ZScore is a "measure of variability"
given the context of the last 30 Days. (or whatever N)

It's an "adaptive scale" where
the the ruler's always adjusting to the most recent data.
The variation it measures, tells you
"how unusually is today's Value relative to the recent median value"

This unusual-ness in measured in units of Standard Deviation (SD).
ZScores series tend to occur (distribute) as a classic "Bell Curve".

And a classic "Bell Curve" has:

68% of events happen between -1 SD and +1 SD
95% of events happen between -2 SD and +2 SD
99% of events happen between -3 SD and +3 SD
and very exceptional stuff is < -3 or > +3 (Thin-tails)

If "Hurst Distribution" applies, instead of a normal "Bell Curve"

then we would likely have Distribution probablities
something like this (just my guestimates):

60% of events happen between -1 SD and +1 SD
90% of events happen between -2 SD and +2 SD
95% of events happen between -3 SD and +3 SD (Fatter-tails)
99% of events happen between -4 SD and +4 SD (Fatter-tails)
and very exceptional stuff is < -4 or > +4 (Fatter-tails)

That's what I know about Z-Scores

I'm still trying to get a theoretical basis
for the Math behind 0-Lag and P-Lag,
which is new adventure for me.
(and part of my motivation for
taking part in the forum)

Mark thanks again
for the constructive comments on the Quiz

To me, I'd be looking at N being 100-300. We're looking for the mean to be a "norm",
i.e. we don't want to get caught out in short trends etc. This flys in the
face of statistical practice of 30.

>and assume P lag is one half the N window:

>= -15 / 15

>= -1

>Not sure was this tells you?? (a measure of probablity?)
Sorry, I wasn't clear on this and I see the confusion. I should have said:

Z Score = Something with no lag minus something smoothed all
divided by something smoothed.
We know that something smoothed has lag, but we're looking at the global picture
of what Z Score is, i.e. which is the major component that effects the Z-Score value.

Because something smoothed by definition changes by small amounts from bar to bar,
e.g. an SMA changes by small amounts bar to bar, then from a "Bar to Bar" perspective, terms 2 and 3 (something smoothed) effect the bar to bar change of
ZScore by a small amount. The only thing that effects the bar to bar change by a large
amount is price itself (which is Zero Lag). So you can call it virtually "zero lag".

I know this sounds like a flimsy argument from the above and I'm sure there's a more
formal mathematical way of putting it, but as they say, the
"Proof is in the eating", so you only have to verify a ZScore against price to see that it
is indeed zero-lag (i.e. peaks and valleys exhibit no lag).

Essentially what I'm looking at in my thinking is the major components in the
indicator and how each contributes to lag, maybe we could come up with some kind of
mathematical set of operations, i.e.:

(and these are just quick guesses)
0 Lag - N Lag = 0 Lag
0 Lag + N Lag = 0 Lag
N Lag * N Lag = N Lag
N Lag (N Lag) = 2^N Lag
0 Lag * N Lag = N / 2 Lag

These set of operations would make it easier to formalize these definitions, by reducing
indicators into these components above so you could figure out an indicators

effect on lag.

If I'm still not being clear enough, let me know and I'll try to formalize the concept another way.

>Is Price less than the SMA of Price?
>(then likely to go up)

>4) Bias_Short_SMA =
>Is Price more than the SMA of Price?
>(then likely to go down)

==========

I believe these Trend_Bias Conditions (previously posted)
may be stated backwards as well. (sorry)

I looked at some of my previous TS,
and usually they GoLong
if Price MORE than the SMA of Price, (not LESS)
and v.v.

I tried to find the Ehler's reference for this,
but could not locate it.

The TS Floorplan I present will still work,
you just may need to try out different indicators
as your Bias and Reversal Indicators.

The Point is This:

If I tell you (or your Mode_Indicator tells you)

"The Market just went in Trend_Mode,
quick Enter a Trade",

What indicator would you use
to tell you if that Trade should Go Long or Go Short?

(without looking at the Chart)

What Yes/No indicator can you use TODAY,
that will tell you the likely
Direction of the Trend,
which is starting today? (There are several)

Whatever indicator you would use
THAT Indicator should become the basis your:

Bias_Long_MyIndicator
Bias_Short_MyIndicator

(3 and 4)

Similar reasoning applies to
to the Reversal Indicators, (used in Cycle_Mode)

If told "the Market just went into Cycle Mode",
what indicator would you use to
determine if the New Position should
be Long or Short? (besides looking at the chart)

This Floorplan should be customized to YOUR own preferences,
think of it as your house,
you need to be comfortable
in the living space.

The TS floorplan has worked for me,
it may work for you as well.

later

James

Re: MARKET MODE and Decision Rules (correction)

Date :8/8/2005 8:23:48 AM Poster : Marcel

James,

Thanks a lot for your detailed description on your "floorplan", really appreciate your candidness and generosity. As you can see in my previous post, I spent the past few days hitting my head against the "brick wall", just to make sure it hasn't become movable or breakable in the meantime... If I don't get other time constraints, I should be able to go through your "floorplan" step by step in the coming days, and I would be glad to revert to you with my findings.

In the meantime – thanks again.
Cheers, Marcel

What's HUP with the Weather?

Date :8/4/2005 10:58:50 AM Poster : James Siebert

Our Weather forecaster just predicted
another "Heat Wave".

In this part of Oregon, a "Heat Wave"
consists of two 90 degree F days in a row.

Since they predicted the last "Heat Wave" correctly,
I'm slightly more inclined to take
this latest prediction more seriously:
(and dress accordingly; keep shades closed, etc)

The prediction looked something like this:

MO TU WE TH FR
H 79 85 91 95 96
L 56 60 65 68 71

Usually the further out the Prediction
the less seriously I take it.
(I usually ignore the Forcast more than a week out)

But since the Actual M, T, W High Temps, this week
were quite close to their Forecasts,

I am wear a Tee-Shirt today at work (Thur).

So what's this got to do with HUP?
(Heinsenburg Uncertainty Principle)

I've always visualized HUP to be a trade-off
between the "Precision & Timeliness" of
constantly changing data. (time series data)

If I wanted, I can always go back and lookup
the Temps from last week with nearly 100% Accuracy,
but the Timeliness of that info would be next to 0.

"Hindsight is always 20-20",
but can this post-dated precison,
help me decide what to wear tommorow?
(a timely decision)

Can I go Hiking this weekend?
or will it be to Hot?
Should I just stay indoors and work on Trading Systems?

These are some of my everyday HUP dilemmas.

On top of that there are some Weather Forecastors
I have more "Confidence" in than others,
even though they all look the same 3-4 Computer Models.
Each weather person "selects" what they see
as "significant" info from the models,
based on what they personally have "learned"
from experience.
(ie their internal NNs shape their individual Forecasts)

Some Practical applications to explore:

If the long-term Trend says
"expect a Hotter and Drier Summer than Normal",
should I invest in more Tee-Shirt,
and plan more trips to the Coast? (where it's cooler).

If an unexpected Cold Front brings in
a string of Cloudy Days, should I
still rely on tommorow's forecast that orignally predicted 90?

Should I put more weight on the Friday evening Forecast,
than the prior Forecasts during the week,
as I am planning my weekend activities?

Hint: the closer the prediction is to occurring, (timeliness)
usually the more confidence I place in it. (accuracy)

What are some other "generalised observations"
can we make about this simple HUP Weather analogy?

How can we extract "signal data" from the past reports,
that might help us more precisely gauge future actions?

How is weekly, monthly, seasonal summary statistics
relevant to planning for next week, next month, next year?

If I give you a prediction like this

MO TU WE TH FR
H 55 51 52 55 53
L 42 44 43 45 42

What can you tell me about the weather pattern?

"You can't know everything,
but that shouldn't stop you from trying." ;)

later,

James Siebert

A superb analogy.

Also, there's another point that applies to trading.

If it's say predicted to be (Canadian version eh :-)):

M - 20C
T - 35C
W - 36C

and you were looking for a warm day then would a prediction with Tuesday being 35C
be more likely to be a warm day (say over 25C), than a prediction for Tuesday of 26C.

I.E. If your prediction mechanism is could, are more extreme predictions
more accurate if you have a general direction you wish to go in?

How Does the Optimize Work

Date :8/10/2005 4:40:20 PM Poster : Maciej

Can anyone explain how the optimizer works? My problem can be summarized as follows:
I setup a trading strategy based simply on entry signals. It gives good results. However I note that it would have been even better if some sort of stop were to be employed.
So I add protective stops to see how to improve matters.
What happens is that my entry signals start disappearing and the results are a significantly degraded.
As my entry signals have been frozen, ie I do not allow any further optimization as I select just the values that have been optimized on the previous optimization I would have expected them to continue to trigger entries in exactly the same way and merely to have the stops optimised.
This does not seem to occur - Can anyone explain?

Re: How Does the Optimize Work

Date :8/16/2005 1:09:20 PM Poster : Maxwel Craven

Any time a stop changes, then you have a different situation with regard to possible re-entry. Ie, you have the ability to get in earlier if you get an entry signal. Am I wrong?

Max

Re: How Does the Optimize Work

Date :8/16/2005 3:35:03 PM Poster : Maciej

The answer is yes and no. If the entry signals were adjustable then your assessment would be correct. However what I'm doing is a two step process whereby I optimize for entries with no stops. I then cast these entries in stone by not allowing any changes, ie range is zero range as from 1 to 1 and add stops with large ranges. I would have expected the optimizer to try to get the ideal stops. This does not seem to happen. Without NSDT, this is the way I work, I get some interesting entry signals and try to improve matters with some money management techniques such as stops.

Re: How Does the Optimize Work

Date :8/17/2005 8:58:53 AM Poster : Maxwell Craven

Do you have any kind of entry and exit rules? Even if you freeze the optimizer, it seems to me that a stop gives the entry rules a chance to execute at an earlier bar than would have been possible without the stop. If any one entry rule has a chance to execute earlier because of the stop, it seems to me the entire sequence could be thrown off. You should be able to compare sequences and see if this is the case.

See if your problem is because you don't have the "Long/Short entries exit existing short/long position" checked. When you have only entries, the entries act as exit signals. But when you have entries and stops, then the stops are the only exit signals unless that option is checked.

Re: How Does the Optimize Work

Date :10/14/2005 2:50:16 AM Poster : vvv999vvv

Hi, Maciej

I experienced the same problem, only way you can achieve good results is simply only SAR entry conditions.

After you optimize your strategy, the range of optimization has changed, if you want to re-optimize it by adding more conditions, change the range of optimization again before you start training, cos the last result's range may limited your optimization.

Another way you can try is add the trailing stop and exit conditions but no train, ie, press cancell after you add the conditions are added.

Pre-processing Data Series: Smoothing

Date :8/11/2005 12:17:15 PM Poster : James Siebert

Now for
Something fun and practical:

For those of you looking
for a easy way to "smooth" your data series
with minimal lag

Ehlers implies a way to do this is:

Smoothed Indicator = (P0 + 2*P1 + 2*P2 + P3) /6

where
P2 = Lag(Price,2)
etc.

He says this
Smoothed Indicator will have only a lag of 1.5 Days

[pg 111 Ehlers, Cybernetic Analysis]

Smoothing attempts to "remove"
the noise from the data series,
leaving you with the "just the Signal"
that is "hidden" in the series.

(I believe this is an example of a FIR Filter
that Mark Simpson referred to earlier.)

I'm a big fan of pre-processing your data.
(the less noise to have,
the more accurate NN & TS Triggers will be. :)

Pre-processing can include
detrending,
filtering,
normalizing,
rescaling,
and of course Z-Scores,
which I feel is one of the easier ways to normalize,
assuming your data follows "random walk" behavior.

(thus the Hurst digression, is this assumption valid?)

Another quick and easy way to Normalize your data that
I've read about recently is called the "Decimalize" method:

NormDecimal = Price / 1000

This has the result of "transforming" your
Price series into an Oscillator, moving between 0.0 & 1.0

Any other Normalization Favorites out there?

I would like to hear about them,
we can exchange recipes.

see ya

James,

That's a good subject to briefly "touch and go", thanks for initiating.

My view is that there are hundreds of smoothers / filters. The choice depends on:
a) What compromise am I willing to take (signal clarity vs lag)?
b) For what objective do I need it?
c) Simple personal preference?

But one thing to consider first is whether you want to smooth Close only, or whether you wish to include OHL, which may also contain important pieces of "information". For a quick and dirty trial I normally use Close, but I like to add OHL (OHLC/4) in the fine-tuning phase. (See also http://www.ward.net/cgi-bin/Forum/Forum_Article.asp?a=2507).

The most important aspect is however that you can't have both at the same time, signal clarity and accuracy (no lag). For reasons we discussed in earlier threads ("What needs to be achieved to build a profitable Neural Net?"), I personally tend not to sacrifice accuracy. A lag of >1 bar is a killer, especially when this signal is then used as input to an indicator, which in turn adds another few bars. If the signal is used standalone (e.g. crossovers), I may however prefer to further reduce noise and accept a higher lag.

Once we have understood the tradeoff between signal clarity and lag and we know for what purpose we need to filter, it's only a matter of personal preference and resources at disposal. Without offending anybody, I'm a little fan of Jurik's products. To quickly smoothen a signal, I'd just average it with a JMA. But again, there are many other alternatives that are comparable.

One interesting option I've stepped into lately is the use of Wavelets as filters.
Try Sub(Close;WaveletFilterHaar(Close;1;100)) or Sub(Close;WaveletFilterHaar(Close;2;100)). The first is still "choppy", but introduces a lag of only 0-1 bars. The second is smoother and the lag is 0-2 bars. If you average both, you may like the output pretty much – it's as good as many expensive indicators...

This is only a little positive side finding while digging into this fascinating chapter. I'm still in an experimental mode wrt Wavelets and I've still lots of material to read on the subject, but I'd appreciate if we could add this topic to the "to-do" list...

Regards,
Marcel

Marcel

Thanks for the WaveletFilterHaar ideas.
I just tried them out, they are very effective smoothers,
with minimal lag. Cool idea.

Thanks for the references on previous threads;
I had skimmed through these before, and
I will review them again, so I can get in sync with
the previous goals and plan of the group.

Sorry if my posts have gone a little off track.
I've only been trying expand on & illustrate ideas
being discussed. I realize Math (& Stats)
are not everyone's favorite subjects.
But it kind of goes with the Neural Net territory.
Most "Killer" systems will have a key Math priniciple(s)
at their core.

Math can (sometimes) be fun.

thanks again for your comments

James Siebert

James,

Again, absolutely no problem with the discussion on Z-Score and Hurst, please continue to do so – It's my problem if I can't contribute... I'm currently testing a model with Z-Scores and although I'm reasonably happy with the signals in a Cycle-Mode, all advantages get wiped off with mistrades (contrarian position taken too early) in the Trend-Phases.

I agree that Math is fun – no question!!

You may wish to try filtering trades based on the value of a trending indicator, such as VHF.

James,

There's tons of very good material on the Web, simply Google with "Wavelets", the best are on the first 3 pages. Based on what's available, I don't think you need to purchase any books. On my side, I'm considering implementing one of the free codes as NST DLL...

Alan

here's the link
to more of the better sites I've seen on wavelets

http://users.rowan.edu/~polikar/WAVELETS/WTtutorial.html

Can't say that I understand all the math that's listed here,

But the conceptual overview (& the impressive 3-D Charts)
helped me to understand how wavelets attempt
to preserve "some of" both "precision and timeliness"
of information conatined in the data signal, concurrently.

Wavelets appear to be a compromise of information,
but may be one of the better "solutions" out there
for "getting around" that brick wall of Heinsenberg.

(the trick here seems to be knowing
"where to look" in the Wavelet's 3 dimensions,
and at what Resolution of details,
to dial in the Wavelet Microscope)

Many thanks to the professor
who posted the site.

hope you find it helpful,
as well.

cheers

James Siebert

Teach a NN to learn RSI or any other indicator

Date :8/13/2005 2:29:36 PM Poster : Marcel

> >- Teach a NN to learn RSI or any other indicator
> These ones we've already discussed to some degree. So lets finish off these.
> Over to you guys.

Well, I will take the 3rd off the list to start. So, let's learn RSI(5), and let me describe how I approached this step by step...

To begin with, I took the default wizard parameters, changed the Output to predict "RSI(Close;5)" and the training objective to "Maximize Correlation", fed the NN with time-delayed changes in Close (change of today, yesterday, day before yesterday etc.) and let it learn. No surprise (can't be that easy right?), correlation close to zero!

I told myself "the guy must have a hard time to translate changes into a bound indicator (0-100) like RSI", so started to add to the input little pieces of the RSI formula, like segregating advancing from declining changes, averaging them out, perform the ratio etc. I tried really many things, but never got a better correlation than 0.1!

After a few hours I had enough – I decided to see what happens if I would feed RSI(5) straight away, anyhow I wasn't that far anymore... Correlation = 0.124. That's when I realized that I was not only teaching the NN to learn RSI, but also to predict it – Mission impossible!

Set the "number of days to predict in future" to zero, return to the initial time-delayed changes in Close for the input, and voila, correlation >0.9! It depends a bit on the underlying data, but current change + 5 delayed changes provides a nice Corr(r) of 0.92, more than enough for me.

But the nice thing is that you can train this same NN to learn – with the same input – other indicators. Most of them compute with a correlation >0.9 (1+5 inputs), some are a bit harder to learn, but adding a few more delayed inputs usually fixes the issue. This includes the indicators found under:
- Price Momentum (good results)
- Change (obviously with perfect results)
- Advanced Change (average results – other input could help)
- And even other more exotic ones

For other category of indicators you have to feed the NN with current + lagged Close prices, instead of changes. This is more appropriate for all categories of "Averages" and those found under "Time Series".

Simplified to the extreme you can say: "For those indicators that you would usually plot in the price section of your TA chart, use the current + lagged PRICE inputs. For those that you would usually display beneath the price chart, use current + lagged CHANGES in price".

Regards,
Marcel

Re: Teach a NN to learn RSI or any other indicator

Date :8/29/2005 9:05:03 PM Poster : Mark Simpson

Hi Marcel,

That's correct. It's quite incredible when you think about it. You only need the input
to an indicator and it's output, and you don't need to know anything about how
the indicator works. It also demonstrates that as long as the relationship is there,
the neural network can learn it extremely effectively.

Marcel and Mark Simpson:

Marcel, thank you very much for bringing this up. It certainly adds a new dimension to the product.

To both Marcel and Mark:

Other than having it learn any indicator (the obvious benefit), what else can this do?

What I mean is, after you have trained it to learn, for example RSI, of what benefit is it to use your new RSI indicator, when your new RSI indicator is simply the old RSI indicator?

John

It's not intended to use instead of RSI, or trade with, it's an exercise in how
NN's learn. Think of it as a test bed. By testing with something that is known, you can experiment to find out what works.
I.E. If you can emulate RSI with a Neural Net, then you can learn what a Neural Net
needs to successfully learn.

Neural nets are very effective at learning things that can be predicted, and very
poor at learning inputs with heavy noise or no or little meaning.

Essentially they way I look at it is, instead of just plugging things into a Neural Network and seeing what works, start from the other way around. Start with something that works, model it, learn why it works, and then you know what you need to find to
make a good model. I.E. A more targetted approach.

However that said, there is one thing that the test bed can be applied to, if you ever
have a black box indicator, then just provide inputs and the black box output to the NN
similar to how you setup RSI, and it will learn it fine. (provided it's a conventional
indicator).

Re: Teach a NN to learn RSI or any other indicator

Date :1/12/2006 8:26:13 PM Poster : Sunny

Mark,

That was brilliant!

I am presumming that you chose no optimization for this prediction.
Do you do walk forwards for this prediction of the RSI(5) using close + lags of close as inputs?
Do you use all available neurons or only some?

Now you have a trained prediction with a high correlation.
(Does it make any difference if you choose instead of maximizing correlation to choose to minimize the average error?)

Do you enter the output of this highly correlated prediction into another prediction as an input?

1st prediction uses close + lags of close as inputs and as the predicted ouput the RSI(5).
2nd prediction uses the out of sample of the 1st prediction as input, and as the predicted output.....?

Do you again try as the predicted output the same RSI(5) or something different?
In this case the number of days to predict in the future is something (1 or more days), and there are some walk forwards....

Regards,

Sunny

To begin with, I took the default wizard parameters, changed the Output to predict "RSI(Close:5)" and the training objective to "Maximize Correlation", fed the NN with time-delayed changes in Close (change of today, yesterday, day before yesterday etc.) and let it learn. No surprise (can't be that easy right?), correlation close to zero!

I told myself "the guy must have a hard time to translate changes into a bound indicator (0-100) like RSI", so started to add to the input little pieces of the RSI formula, like segregating advancing from declining changes, averaging them out, perform the ratio etc. I tried really many things, but never got a better correlation than 0.1!

After a few hours I had enough – I decided to see what happens if I would feed RSI(5) straight away, anyhow I wasn't that far anymore... Correlation = 0.124. That's when I realized that I was not only teaching the NN to learn RSI, but also to predict it – Mission impossible!

Set the "number of days to predict in future" to zero, return to the initial time-delayed changes in Close for the input, and voila, correlation >0.9! It depends a bit on the underlying data, but current change + 5 delayed changes provides a nice Corr(r) of 0.92, more than enough for me.

But the nice thing is that you can train this same NN to learn – with the same input – other indicators. Most of them compute with a correlation >0.9 (1+5 inputs), some are a bit harder to learn, but adding a few more delayed inputs usually fixes the issue. This includes the indicators found under:
- Price Momentum (good results)
- Change (obviously with perfect results)
- Advanced Change (average results – other input could help)
- And even other more exotic ones

For other category of indicators you have to feed the NN with current + lagged Close prices, instead of changes. This is more appropriate for all categories of "Averages" and those found under "Time Series".

Simplified to the extreme you can say: "For those indicators that you would usually plot in the price section of your TA chart, use the current + lagged PRICE inputs. For those that you would usually display beneath the price chart, use current + lagged CHANGES in price".

> I am presumming that you chose no optimization for this prediction.
Correct.

>Do you do walk forwards for this prediction of the RSI(5) using close + lags of close as inputs?
Yes

>Do you use all available neurons or only some?
I use the default, although extra neurons won't make much difference anyway, because
the neural network doesn't have an issue learning the relationship.

>Now you have a trained prediction with a high correlation.
(>Does it make any difference if you choose instead of maximizing correlation to choose
> to minimize the average error?)
I haven't tried it, but essentially it shouldn't make much difference.

The key is that you have zero noise because your training data (RSI) is an exact calculation on the input (close and lags of close). When a neural network has everything it needs,
essentially tweaking the controls won't make too much change. When the neural network doesn't
have everything it needs, tweaking the controls can make a huge difference, but you can't
necessarily trust the results either.

>Do you enter the output of this highly correlated prediction into another prediction
> as an input?
You could do. But remember, you can't trade this. It's an exercise. All you've done is
built a NN to learn RSI, and just using the RSI indicator (without an NN) will produce a slightly
superior result.

Re: Teach a NN to learn RSI or any other indicator

Date :1/13/2006 10:23:22 AM Poster : Steve Ward

Mark said: "Neural nets are very effective at learning things that can be predicted, and very poor at learning inputs with heavy noise or no or little meaning."

I'm not as concerned about noise as Mark is, because nets have actually long been used for signal noise removeal. It may depend on what "heavy" means, but I'm more concerned about non-repeating patterns, which is certainly one case of "little or no meaning". I have two charts in the attachment to illustrate.

Click here to download the illustration charts

First I built a text file with repeating numbers x, then made a sine wave from them sin(x). Sin(x) goes from -1 to 1, so I added +- 0.3 to the sin wave as noise. I loaded them into a chart which is "repeat patterns with noise (data saved).chf". Given the repeating pattern as the single input, I predicted the noisy sine wave, including 1 year out-of-sample evaluation. As you can see, the prediction cleaned up all the noise and produced a pretty clean sine wave. You can repeat the experiment with even bigger noise if you want to, or try more hidden neurons for tighter fitting.

Next I made a non-repeating series of incrementing numbers (I hate to call that a pattern) and made a sine wave from them. They are in the chart "non-repeating patterns (data saved).chf", I inserted another prediction where I tried to predict even the non-noisy sine wave using the non-repeating numbers as the input. As you can see, the net failed miserably - it had no idea what the pattern was. Why? Because if patterns don't repeat, the net has no way of extrapolating the non-linear curve. The output repeated, but the input didn't.

Of course if you do some preprocessing on the non-repeating numbers, like dividing them by 6.28318, and making the remainder of that division the one input, then the net works because the patterns now repeat. (The math geeks among you will understand what I did.)

The moral of the story - neural nets only work where there are historical patterns of input/output pairs that repeat over time, even if they are noisy.

>John

It's not intended to use instead of RSI, or trade with, it's an exercise in how
NN's learn. Think of it as a test bed. By testing with something that is known, you can experiment to find out what works.
I.E. If you can emulate RSI with a Neural Net, then you can learn what a Neural Net
needs to successfully learn.

Neural nets are very effective at learning things that can be predicted, and very
poor at learning inputs with heavy noise or no or little meaning.

Essentially they way I look at it is, instead of just plugging things into a Neural Network and seeing what works, start from the other way around. Start with something that works, model it, learn why it works, and then you know what you need to find to
make a good model. I.E. A more targetted approach.

However that said, there is one thing that the test bed can be applied to, if you ever
have a black box indicator, then just provide inputs and the black box output to the NN
similar to how you setup RSI, and it will learn it fine. (provided it's a conventional
indicator).

One question on normalization

Date :8/14/2005 11:18:55 PM Poster : Alan Rhodes

I have been reading lots of great posts since clearing my head from dust from working on forest fires (action too slow to get much smoke). Though I could use a little slowing down overall in the rate of new subjects, I do have one question.

Several of the posts imply that predictions should be totally normalized (I define that as zero based). I do not understand why that is good.

It seems to me that would work well during a cycle mode, but during a trending mode I would expect the prediction to drift around zero in whatever method you use to normalize the data.

Earlier one person suggested using the culmination of percent change. I am going to work on developing a variation of that. I tried that once and got the same problem I had with other non-normalized predictions. The problem with many non-normalized predictions is that the best predictors are the current values of what you are predicting. In other words, if the current value of what you are predicting goes up, the neural network raises the value of prediction. If the current value goes down, the prediction goes down.

Also earlier Mark implied that Z-Score based systems can fall apart during trending mode. This is probably related to the fact that such systems are by nature zero based.

Curve fitting. What it is, how to avoid it and how to use it to advantage

Date :8/30/2005 2:24:54 PM Poster : Mark Simpson

This thread is about curve fitting. I also refer you to Steve Ward's tips on preventing over-optimization http://www.ward.net/cgi-bin/viewtip.asp?ID=105 as a guideline for what you can do to avoid it.

So, lets start off with what a GA (Genetic Algorithm) is, to remove some of the mysticism behind the GA built into Neuroshell. Personally I believe that it's by understanding the principles of this that it can be better used to advantage. The GA is a very powerful tool if used correctly, if used incorrectly it can sink you.

You've probably come across the following problem, you build your system, keep optimizing various types of system until you find one that does well, then you trade it in realtime, and poof, that well performing system eats you alive. If you've done everything else correctly, i.e. tested on out samples and used walk forwards, then the chances are you've just incorrectly curve fitted without realizing it.

So what is curve fitting? If you imagine your trading system like this, you have inputs and you have an output (trading signals). You have a black box in the middle which translates between. Essentially the output is a function of the input. I.E. Output=f (Input1..Input N)

The output is the curve, i.e. it's a varying function, and the idea is that we have to design the function so that it fits that curve.

So, lets translate this to the NST world. We use a bunch of indicators to go into our "function", and then see how well the function works (performance). However it doesn't do too well, so we use the optimization feature in NST (a GA) to alter the parameters to the indicators to make the function fit the curve better.

A Genetic Algorithm (GA) is just a tool to reduce the search space. For instance if you had 5 indicators with a total of 10 possible parameters, then to try every possible combination would take a long time. Trying every possibility is a brute force method and isn't practical unless your model is extremely simple.

A GA looks at the problem differently. If we wanted to find the highest peak in a range of mountains, then visiting every mountain takes too long, so a GA uses a targetted approach. I.E. You guess a local peak to begin with. It probably isn't the highest peak, so you guess again. Then using a chromosome/gene model borrowed from biology, where you have survival of the fittest, you match the good parameters of the mountains and keep going. Essentially you keep going, at every generation, the fittest members survive to keep going, until you can make no more "reasonable" improvement. I.E. Your solution evolves to find the best answer just like life on earth. What's happening is your taking spot readings over the range and homing in on the highest mountain.

A GA has a fitness function (in this case the height of the mountain), in the case of trading, it's your goal. The GA is a tool to help us fit the curve. A brute force method can be better than a GA, but if a GA doesn't reach the correct answer, it will likely reach one that's close. I.E. In the trade off between brute force and a GA, GA is really only the practical way to go, although brute force may be occasionally a little more superior in result.

So lets try some examples of incorrectly curve fitting with a few examples.

CURVE FITTING WITH TOO LITTLE DATA:

So we toss some coins. Coins can be heads or tails and our goal is to build a perfect coin toss predictor. We toss 3 times, and get heads each time. Therefore we optimize our solution, and build a perfect coin tosser that always generates heads as the answer. So what's wrong?

Well, our curve is heads/tails, but we took such a small sample (of size 3), that we didn't see the real picture. I.E. We tried to fit a curve where we couldn't see the whole curve. In trading, this is a classic mistake that is commonly made. We genetically optimize with not enough data. Remember from before that to be reasonably confident that we haven't incorrectly curve fitted the data, we need 30 trades per degree of freedom (DOF) for every variable in the model.

This shows up as, building a model that optimizes well, then trades poorly in real time. If you tested with adequate data, you'd have found out that it really was poor in the first place.

CURVE FITTING BY SELECTION: STOCK PICKING

We can also incorrectly curve fit by picking results, without even using a GA.

For instance, if you were to trade say 10 stocks randomly for a period of time, you'd likely make money on some and lose money on others. Just like tossing a coin would produce heads and tails.

So you have your perfect model and you want to trade, but it works on some stocks not others, so you plug in 100 stocks to find out which ones do well and which ones do poorly, and keep the good ones. Well you've just incorrectly curve fitted by another means. (or another way of looking at it is rendered your out of sample to be in sample). This is because out of any population (the 100), if you pick and choose your sample (the good ones), then your sample is no longer truely representative of your population.

CURVE FITTING BY SELECTION: INDICATORS

So, instead of picking the best stocks to use in your model, you pick the best indicators, i.e. just keep plugging at it until you find indicators that work.

Again, just another form of incorrect curve fitting for the same reason as the last.

CURVE FITTING BY SELECTION: PICKING THE BEST RESULTS

So you keep trying models until you find the best one. Again, just incorrectly curve fitting.

As you can see, this is a huge problem, there are so many ways to incorrectly curve fit. Anywhere where you pick and choose, or try different things open you up to curve fitting.

One solution might be to create another out of sample testing to get around the problem. But again, if you pick and choose between those out of samples, you're opening yourself up to the same problem again.

So, incorrectly curve fitting is not 100% avoidable, but needs to be realized and managed. Personally I follow this method to avoid it as much as possible:

1. Never try things out in a model in an untargetted approach, and this is where these threads about design models come into the picture. Start off with a goal, and design a model to fit that goal, don't just guess at methods or indicators that will work, start off with solid design from the ground up.

2. Use a GA to improve good models, not to make bad models work.

3. If using a GA, use it at the end of the process, i.e. as a final improvement to an already good model.

4. Use sufficient data to test with.

5. Always keep additional out of samples to test on. A good out of sample is always paper trading.

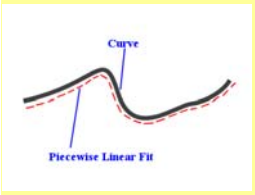
6. Never pick and choose results, stocks or anything else. (At least not without being aware of it and knowing the effect).

7. Keep degrees of freedom low. I.E. The smaller the DOF, the less data you need to validate which makes everything a lot simpler to test.

USING CURVE FITTING TO ADVANTAGE:

There is another way to approach curve fitting and make it work to your advantage. At first it seems like a crazy approach, but there are good reasons why it works. That is to keep DOF small and optimize frequently.

The reason for this is because of the curve fitting. Normally we wish to fit that curve perfectly, however, any curve can be approximated by a series of small lines. This is called a Piecewise Linear Approach. Linear = Line, Piecewise means small pieces.



I.E. If you keep Degrees Of Freedom (DOF) low so that your fit can be validated in minimal time, i.e. you're creating a small line, then it can fit (approximately) the curve of your function for a small period of time. You then reoptimize frequently to get additional small segments of lines.

Re: Curve fitting. What it is, how to avoid it and how to use it to advantage

Date :8/31/2005 6:23:43 PM Poster : James Siebert

Mark

Glad to see your in-depth explanation on "curve fitting"

Thanks a lot. It helps.

I never knew there were so many ways to
run into this problem.

I especially like your description
of the "finding the highest peak in a range of mountains"

-attached are a couple of xls I put together,
to illustrate some Mountain Terrains
in the SMA parameter space - SMA_Lanscapes.zip

I have always visualized that NN train,
by "rolling a marble around" in a Parameter Solution Space,
trying to find the Lowest spot, in that terrain.

The Lowest spot represents the "Minimum Prediction Error",
for the given combination of Input Parameters,
intersecting at that point.

Sometimes "the marble gets stucks" in a local valley,
before it finds the actual bottom (a lower valley)

Some questions

1) when NN get stuck at such a local minimums,
does it help to:

a) increase training time

b) increase number neurons

c) increase walk-forwards episodes

d) increase data inputs

e) change training objective

f) reduce net inputs

2) how often should NN be re-trained,
when the Solution Space Terrain may change over time?
(for example, a stock SMA may change Cycles
from 30 day to 50 days, in a matter of weeks)

3) Is curve-fitting, getting stuck in a local Minimum,
or stuck in a "stale or obsolete" Prediction Terrain?
Or something else entirely?

4) Does the Piece-Wise Curve fitting you describe
have anything to with using/retraining
with very short Time Horizons?
(fitting short time window Nets to the "ideal curve",
what ever "the ideal" is)

Thanks in advance,
for any more light you can shed on this subject

James Siebert

A GA has a fitness function (in this case the height of the mountain), in the case of trading, it's your goal. The GA is a tool to help us fit the curve. A brute force method can be better than a GA, but if a GA doesn't reach the correct answer, it will likely reach one that's close. I.E. In the trade off between brute force and a GA, GA is really only the practical way to go, although brute force may be occasionally a little more superior in result.

So lets try some examples of incorrectly curve fitting with a few examples.

CURVE FITTING WITH TOO LITTLE DATA:

So we toss some coins. Coins can be heads or tails and our goal is to build a perfect coin toss predictor. We toss 3 times, and get heads each time. Therefore we optimize our solution, and build a perfect coin tosser that always generates heads as the answer. So what's wrong?

Well, our curve is heads/tails, but we took such a small sample (of size 3), that we didn't see the real picture. I.E. We tried to fit a curve where we couldn't see the whole curve. In trading, this is a classic mistake that is commonly made. We genetically optimize with not enough data. Remember from before that to be reasonably confident that we haven't incorrectly curve fitted the data, we need 30 trades per degree of freedom (DOF) for every variable in the model.

This shows up as, building a model that optimizes well, then trades poorly in real time. If you tested with adequate data, you'd have found out that it really was poor in the first place.

CURVE FITTING BY SELECTION: STOCK PICKING

We can also incorrectly curve fit by picking results, without even using a GA.

For instance, if you were to trade say 10 stocks randomly for a period of time, you'd likely make money on some and lose money on others. Just like tossing a coin would produce heads and tails.

So you have your perfect model and you want to trade, but it works on some stocks not others, so you plug in 100 stocks to find out which ones do well and which ones do poorly, and keep the good ones. Well you've just incorrectly curve fitted by another means. (or another way of looking at it is rendered your out of sample to be in sample). This is because out of any population (the 100), if you pick and choose your sample (the good ones), then your sample is no longer truely representative of your population.

CURVE FITTING BY SELECTION: INDICATORS

So, instead of picking the best stocks to use in your model, you pick the best indicators, i.e. just keep plugging at it until you find indicators that work. Again, just another form of incorrect curve fitting for the same reason as the last.

CURVE FITTING BY SELECTION: PICKING THE BEST RESULTS

So you keep trying models until you find the best one. Again, just incorrectly curve fitting.

As you can see, this is a huge problem, there are so many ways to incorrectly curve fit. Anywhere where you pick and choose, or try different things open you up to curve fitting.

One solution might be to create another out of sample testing to get around the problem. But again, if you pick and choose between those out of samples, you're opening yourself up to the same problem again.

So, incorrectly curve fitting is not 100% avoidable, but needs to be realized and managed. Personally I follow this method to avoid it as much as possible:

1. Never try things out in a model in an untargetted approach, and this is where these threads about design models come into the picture. Start off with a goal, and design a model to fit that goal, don't just guess at methods or indicators that will work, start off with solid design from the ground up.

2. Use a GA to improve good models, not to make bad models work.

3. If using a GA, use it at the end of the process, i.e. as a final improvement to an already good model.

4. Use sufficient data to test with.

5. Always keep additional out of samples to test on. A good out of sample is always paper trading.

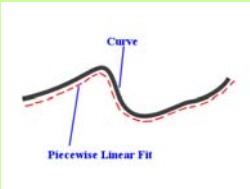
6. Never pick and choose results, stocks or anything else. (At least not without being aware of it and knowing the effect).

7. Keep degrees of freedom low. I.E. The smaller the DOF, the less data you need to validate which makes everything a lot simpler to test.

USING CURVE FITTING TO ADVANTAGE:

There is another way to approach curve fitting and make it work to your advantage. At first it seems like a crazy approach, but there are good reasons why it works. That is to keep DOF small and optimize frequently.

The reason for this is because of the curve fitting. Normally we wish to fit that curve perfectly, however, any curve can be approximated by a series of small lines. This is called a Piecewise Linear Approach. Linear = Line, Piecewise means small pieces.



I.E. If you keep Degrees Of Freedom (DOF) low so that your fit can be validated in minimal time, i.e. you're creating a small line, then it can fit (approximately) the curve of your function for a small period of time. You then reoptimize frequently to get additional small segments of lines.

>I especially like your description
>of the "finding the highest peak in a range of mountains"
That one I've seen in a few places in descriptions of GA, so it's not my description as such.

>-attached are a couple of xls I put together,
>to illustrate some Mountain Terrains
>in the SMA parameter space - Those are good charts. You have a knack of visualizing these things well.

>Sometimes "the marble gets stucks" in a local valley,
>before it finds the actual bottom (a lower valley)

>Some questions

>1) when NN get stuck at such a local minimums,
>does it help to:

>a) increase training time
I'd guess a yes on this one (depending on the neural net architecture being used).

>b) increase number neurons
I'd say yes on this one. (though not guaranteed in every case).

>c) increase walk-forwards episodes
If you train on different data, you could get different results, so I'd say yes.

>d) increase data inputs
Again, different data, so I'd say yes.

>e) change training objective
Different data, so different surface for the ball to move around on so yes.

>f) reduce net inputs
Different data, so again yes.

Those are my gut reactions. However, the key point is change the data, and you'll likely either end up in a different local minimum, or the global minimum.

Bear in mind that a local minimum may not be bad if global minimum - local minimum approaches zero.

The other thing I'd like to add is that the settling in a local minimum can be highly dependant on these 2 things:

1. The type of Neural network you're using. Some handle learning better than others.

2. The shape of the surface. I.E. A surface that is busy is more likely to have local minima, than a surface which is flat or curved.

>2) how often should NN be re-trained,
>when the Solution Space Terrain may change over time?
>(for example, a stock SMA may change Cycles
>from 30 day to 50 days, in a matter of weeks)

1. My initial reaction on this would be to wait for the discussion on Time Normalization, and the answer will become clearer, however in the meantime:

In theory if you had everything correct, then why would a NN need to be retrained? So that begs the question, what's changing to require the need to retrain? I.E. Why is the solution space terrain changing over time? ;-)

NN's we've figured out before are simple function imitators. So if the function we're using is varying over time, either we should fix that OR supply some indicator (an adaptor) which measures the adaptation in the function to the NN OR piecewise linear fit it.

The only problem with piecewise linear fitting an NN using backprop, is the amount of time needed to adequately train and test(walkforwards) an NN, which means that the pieces are generally too long. So backprop generally doesn't work too well for piecewise linear fitting unless the function varies extremely slowly over time. So generally piecewise linear fitting is best done with the GA instead of an NN.

>3) Is curve-fitting, getting stuck in a local Minimum,
>or stuck in a "stale or obsolete" Prediction Terrain?
>Or something else entirely?
Curve fitting means different things to different people. My interpretation is that if you've reached a local minima that is acceptable, then you've curve fitted your function (which is good). If your local minima is not acceptable, then you've incorrectly curve fitted (or poorly curve fitted).

So if you took an NN, the data you're training against, or your out of sample is the function you're trying to approximate, and your NN output is what you're trying to approximate it with. So say you were training on 6 day percent change in close, then the actual 6 day percent change in close would be the function you're approximating, and the NN's prediction of a 6 day percent change would be your approximation. The accuracy of your prediction would be how well you curve fitted. If you did something incorrect in your thinking, e.g. didn't use enough training data and got a good approximation, then you've curve fitted well (got a good result), but you've incorrectly curve fitted becuase of the method used.

That's for an NN, for a trading strategy, then it's all about trades. Your optimization objective is your actual, and your strategy results are your appoximation.

>4) Does the Piece-Wise Curve fitting you describe
>have anything to with using/retraining
>with very short Time Horizons?
>(fitting short time window Nets to the "ideal curve",
>what ever "the ideal" is)
Correct. It's the same thing. The piece-wise curve fitting is the reason why it works.
The example I provided used a GA, but the principle can be applied to NN's and
other techniques.

Mark

Thanks for your detailed replies to my questions,
about Solutions Terrains and Local Minimums.

Your answers made me realize that
curve-fitting is not necessarily a "bad thing".
A well-trained NN will in effect
be a "substitute curve" for the actual input factors
and their complex interactions.

The closer the "substitute" (NN) represents
the "actual" behavoir, the more predictive power it will have.

Optimization allows the substitute terrain
to "form-fit" to the actual terrain.

So when does "over-optimization" occur, with negative effect?

Until recently I though this had something to do
the NN "memorizing the data", as opposed to
"responding to it" in a natural, inherit way

Now it seems "the closer the curve the better"
should be the rule of thumb (?)
(assuming inputs, actually models
existing dependant relationships)

==========

Regarding your Comments:

>>>>>>>>
>The other thing I'd like to add is that the settling in a local minimum can be highly
>dependant on these 2 things:

>1. The type of Neural network you're using. Some handle learning better than others.
>>>>>>>>

What are some different Types?
TDNN, Crossovers, Market Mode Filtering,
Correlated Inputs, Signal Components, etc?

Or by "Type" are you referring to
Objectives, Neurons, # of Inputs,
# of Walk-forwards, level of Optimization?

Comment 2:

>>>>>>>>>
>>2) how often should NN be re-trained,
>>when the Solution Space Terrain may change over time?
>>(for example, a stock SMA may change Cycles
>>from 30 day to 50 days, in a matter of weeks)

Hi James

>Your answers made me realize that
>curve-fitting is not necessarily a "bad thing".
>A well-trained NN will in effect
>be a "substitute curve" for the actual input factors
>and their complex interactions.
A piecewise linear approach works, however DOF must be small, otherwise
the pieces are too large to fit. I.E. you can't piecewise linear fit a sine wave with
a line that is half the cycle length. However you could fit it with a line that is 1/100 of
the cycle in length.

So in reality, most models have too much DOF to be viable for a piecewise linear fit
approach. You really want to be aiming for 1 DOF to be viable, i.e. "30 trades" to test
in most cases. Because each line piece has to be statistically valid as well as small
to be assured that the model works.

>Regarding your Comments:

>>>>>>>>
>The other thing I'd like to add is that the settling in a local minimum can be highly

>Or by "Type" are you referring to
>Objectives, Neurons, # of Inputs,
># of Walk-forwards, level of Optimization?

I mean architecture of neural nets/learning methods. I.E. Back propogation,
LVQ, PNN, GNN, Kohonen etc. They have different learning methods, so
some are better at local minima type issues than others for a particular solution.

>Don't Market Behavoirs change over-time?
>one model can't anticipate those changes, can it?
>(ex. Sector Rotation, or Spectuaition Bubbles bursting, etc)

>Another way of putting this,
>How often should a NN be retrained,
>and for what reasons?

Yes, market behaviours do change over time, but this change is a variable, and if
you can quantify it and measure it, then you are essentially either giving the neural
net the ability to account for this via an extra input, or you fix the data for this before
providing it to the NN, in which case the NN need not change. Remember that
a NN can only reproduce what it has learnt before. If you don't account for this, then you're left with either trading things that don't change their behaviour, or using a piecewise linear approach.

In my opinion, a lot of the reasoning for people saying, the "market changes over time",
is because of people assuming that time is linear. They are too tied to a clock concept. The market has a "rate", which will become apparent when we discuss time normalization when the curve fitting/piecewise linear discussion is wrapped up.

I really wanted to save this to the time normalization discussion, but as a taster, consider the following. Regarding the bubble, if the bubble was stretched out and the surrounding area compressed, is it still a bubble? What happens to indicators
during bubbles? I.E. Should you be using indicators with shorter periods, or
longer periods during a bubble? Are things the same pre, bubble and post? How
could they be made the same to remove the bubble? We'll answer these questions.

Re: Curve fitting. What it is, how to avoid it and how to use it to advantage

Date :10/21/2005 9:33:41 AM Poster : Dan

Mark,

I really appreciate your helpful tip regarding 30 trades per DOF, and read another of your articles that suggests: "Calculate the number of Degrees of Freedom in your model (DOF) - aka variables, and validate the model with 30 trades per degree of freedom."

I wonder if you could clarify how to calculate DOF. Does one simply count each indicator in a system as one variable, or, in the case of indicators that have more than one optimizable parameter does one count every optimizable parameter in every indicator as a variable?

Thanks again for the helpful articles,

Dan

On 8/30/2005 2:24:54 PM Mark Simpson wrote:
This thread is about curve fitting, I also refer you to Steve Ward's tips on preventing
over-optimization http://www.ward.net/cgi-bin/viewtip.asp?ID=105 as a guideline for
what you can do to avoid it.

So, lets start off with what a GA (Genetic Algorithm) is, to remove some of the mysticism behind the GA built into Neuroshell. Personally I believe that it's
by understanding the principles of this that it can be better used to advantage.
The GA is a very powerful tool if used correctly, if used incorrectly it can sink
you.

You've probably come across the following problem, you build your
system, keep optimizing various types of system until you find one that does well,
then you trade it in realtime, and poof, that well performing system eats you alive.

If you've done everything else correctly, i.e. tested on out samples and used walk forwards, then the chances are you've just incorrectly curve fitted without realizing it.

So what is curve fitting? If you imagine your trading system like this, you
have inputs and you have an output (trading signals). You have a black box in the middle which translates between. Essentially the output is a function
of the input. I.E. Output=f (Input1..Input N)

The output is the curve, i.e. it's a varying function, and the idea is that we have to
design the function so that it fits that curve.

So, lets translate this to the NST world. We use a bunch of indicators to go into
our "function", and then see how well the function works (performance). However
it doesn't do too well, so we use the optimization feature in NST (a GA) to alter
the parameters to the indicators to make the function fit the curve better.

A Genetic Algorithm (GA) is just a tool to reduce the search space. For instance
if you had 5 indicators with a total of 10 possible parameters, then to try every
possible combination would take a long time. Trying every possibility is a brute force
method and isn't practical unless your model is extremely simple.

A GA looks at the problem differently. If we wanted to find the highest peak in a range of mountains, then visiting every mountain takes too long, so a GA
uses a targetted approach. I.E. You guess a local peak to begin with. It probably
isn't the highest peak, so you guess again. Then using a chromosome/gene
model borrowed from biology, where you have survival of the fittest, you match the good parameters of the mountains and keep going. Essentially you keep going, at every generation, the fittest members survive to keep going, until you can make no more "reasonable" improvement. I.E. Your solution evolves to find the best answer
just like life on earth. What's happening is your taking spot readings over the range
and homing in on the highest mountain.

A GA has a fitness function (in this case the height of the mountain), in the case of
trading, it's your goal. The GA is a tool to help us fit the curve. A brute force method can be better than a GA, but if a GA doesn't reach the correct answer, it will likely
reach one that's close. I.E. In the trade off between brute force and a GA, GA is
really only the practical way to go, although brute force may be occasionally a little
more superior in result.

So lets try some examples of incorrectly curve fitting with a few examples.

CURVE FITTING WITH TOO LITTLE DATA:

So we toss some coins. Coins can be heads or tails and our goal is to build a perfect
coin toss predictor. We toss 3 times, and get heads each time. Therefore we
optimize our solution, and build a perfect coin tosser that always generates heads
as the answer. So what's wrong?

Well, our curve is heads/tails, but we took such a small sample (of size 3), that
we didn't see the real picture. I.E. We tried to fit a curve where we couldn't see the whole curve. In trading, this is a classic mistake that is commonly made. We genetically optimize with not enough data. Remember from before that to be
reasonably confident that we haven't incorrectly curve fitted the data, we need
30 trades per degree of freedom (DOF) for every variable in the model.

This shows up as, building a model that optimizes well, then trades poorly in real time.
If you tested with adequate data, you'd have found out that it really was poor in the
first place.

CURVE FITTING BY SELECTION: STOCK PICKING

We can also incorrectly curve fit by picking results, without even using a GA.

For instance, if you were to trade say 10 stocks randomly for a period of time,
you'd likely make money on some and lose money on others. Just like tossing
a coin would produce heads and tails.

So you have your perfect model and you want to trade, but it works on some stocks
not others, so you plug in 100 stocks to find out which ones do well and which ones
do poorly, and keep the good ones. Well you've just incorrectly curve fitted by
another means. (or another way of looking at it is rendered your out of sample to be in sample). This is because out of any population (the 100), if you pick and choose your sample (the good ones), then your sample is no longer truely representative of your population.

CURVE FITTING BY SELECTION: INDICATORS

So, instead of picking the best stocks to use in your model, you pick the best indicators, i.e. just keep plugging at it until you find indicators that work.
Again, just another form of incorrect curve fitting for the same reason as the
last.

CURVE FITTING BY SELECTION: PICKING THE BEST RESULTS

So you keep trying models until you find the best one. Again, just incorrectly curve fitting.

As you can see, this is a huge problem, there are so many ways to incorrectly
curve fit. Anywhere where you pick and choose, or try different things open you
up to curve fitting.

One solution might be to create another out of sample testing to get around the problem. But again, if you pick and choose between those out of samples, you're
opening yourself up to the same problem again.

So, incorrectly curve fitting is not 100% avoidable, but needs to be realized and
managed. Personally I follow this method to avoid it as much as possible:

1. Never try things out in a model in an untargetted approach, and
this is where these threads about design models come into the picture. Start off
with a goal, and design a model to fit that goal, don't just guess at methods or
indicators that will work, start off with solid design from the ground up.

2. Use a GA to improve good models, not to make bad models work.

3. If using a GA, use it at the end of the process, i.e. as a final improvement to an
already good model.

4. Use sufficient data to test with.

5. Always keep additional out of samples to test on. A good out of sample is
always paper trading.

6. Never pick and choose results, stocks or anything else. (At least not without
being aware of it and knowing the effect).

7. Keep degrees of freedom low. I.E. The smaller the DOF, the less data you
need to validate which makes everything a lot simpler to test.

USING CURVE FITTING TO ADVANTAGE:

There is another way to approach curve fitting and make it work to your advantage. At first it seems like a crazy approach, but there are good reasons why it works. That is to keep DOF small and optimize frequently.

The reason for this is because of the curve fitting. Normally we wish to fit that curve perfectly, however, any curve can be approximated by a series of small lines. This is
called a Piecewise Linear Approach. Linear = Line, Piecewise means small pieces.

I.E. If you keep Degrees Of Freedom (DOF) low so that your fit can be validated in minimal time, i.e. you're creating a small line, then it can fit (approximately) the curve
of your function for a small period of time. You then reoptimize frequently to get additional small segments of lines.

Hi Dan,

DOF means a lot of different things to different people, however the way I approach
it is as follows.

To me a degree of freedom is an item that can change in a model. This could be:
1. A parameter to an indicator
2. Choice of indicator
3. Choice of security

All this is pretty vague, so hopefully the following examples will clarify it:

Model Inputs: RSI(x) on 1 security where x is optimized.
Answer: 1 DOF as x is a variable parameter i.e. it can change.

Model Inputs: RSI(5) on 1 security.
Answer: 1 DOF (as you need to validate the model on something).

Model Inputs: MACD(close,12,26) on 1 security
Answer: 1 DOF (as you need to validate the model on something).

Model Inputs: MACD(close,x,y) on 1 security where x/y are optimized.
Answer: 2 DOF (x and y)

Model Inputs: MACD(RSI (z), x, y) on 1 security where z/x/y are optimized.
Answer: 3 DOF (x, y and z)

Model Inputs: MACD (RSI (z), x, y) where z/x/y are optimized, and then we try
different stocks against it to find which ones perform best.
Answer: 4 DOF (x,y,z and stock selection)

Model Inputs: Indicator(x) where x is optimized, and we try many different indicators
to find one that works on 1 security.
Answer: 2 DOF (x and Indicator selection)

Model Inputs: MACD(close,5,20) where we just guessed 5,20 as being the parameters
on 1 security.
Answer: 1 DOF (as you need to validate the model on something)

Model Inputs: MACD(close,5,20) however, we tried many different values for 5 and 20 until we found the ones that worked on 1 security.
Answer: 2 DOF (becuase you were manually changing both the 5 and 20).

So if you let the optimizer choose a value, 1 DOF gets added. If you
manually choose a value through experimentation, 1 DOF gets added.

Hi Dan,

DOF means a lot of different things to different people, however the way I approach
it is as follows.

To me a degree of freedom is an item that can change in a model. This could be:
1. A parameter to an indicator
2. Choice of indicator
3. Choice of security

All this is pretty vague, so hopefully the following examples will clarify it:

Model Inputs: RSI(x) on 1 security where x is optimized.
Answer: 1 DOF as x is a variable parameter i.e. it can change.

Model Inputs: RSI(5) on 1 security.

Answer: 1 DOF (as you need to validate the model on something).

Model Inputs: MACD(close,12,26) on 1 security
Answer: 1 DOF (as you need to validate the model on something).

Model Inputs: MACD(close,x,y) on 1 security where x/y are optimized.
Answer: 2 DOF (x and y)

Model Inputs: MACD(RSI (z), x, y) on 1 security where z/x/y are optimized.
Answer: 3 DOF (x, y and z)

Model Inputs: MACD (RSI (z), x, y) where z/x/y are optimized, and then we try
different stocks against it to find which ones perform best.
Answer: 4 DOF (x,y,z and stock selection)

Model Inputs: Indicator(x) where x is optimized, and we try many different indicators
to find one that works on 1 security.
Answer: 2 DOF (x and Indicator selection)

Model Inputs: MACD(close,5,20) where we just guessed 5,20 as being the parameters
on 1 security.
Answer: 1 DOF (as you need to validate the model on something)

Model Inputs: MACD(close,5,20) however, we tried many different values for 5 and 20 until we found the ones that worked on 1 security.
Answer: 2 DOF (becuase you were manually changing both the 5 and 20).

So if you let the optimizer choose a value, 1 DOF gets added. If you
manually choose a value through experimentation, 1 DOF gets added.

This thread is about curve fitting. I also refer you to Steve Ward's tips on preventing
over-optimization http://www.ward.net/cgi-bin/viewtip.asp?ID=105 as a guideline for
what you can do to avoid it.

So, lets start off with what a GA (Genetic Algorithm) is, to remove some of the mysticism behind the GA built into Neuroshell. Personally I believe that it's
by understanding the principles of this that it can be better used to advantage.
The GA is a very powerful tool if used correctly, if used incorrectly it can sink
you.

You've probably come across the following problem, you build your
system, keep optimizing various types of system until you find one that does well,
then you trade it in realtime, and poof, that well performing system eats you alive.
If you've done everything else correctly, i.e. tested on out samples and used walk forwards, then the chances are you've just incorrectly curve fitted without realizing it.

So what is curve fitting? If you imagine your trading system like this, you
have inputs and you have an output (trading signals). You have a black box in the middle which translates between. Essentially the output is a function
of the input. I.E. Output= (Input1..Input N)

The output is the curve, i.e. it's a varying function, and the idea is that we have to
design the function so that it fits that curve.

So, lets translate this to the NST world. We use a bunch of indicators to go into
our "function", and then see how well the function works (performance). However
it doesn't do too well, so we use the optimization feature in NST (a GA) to alter
the parameters to the indicators to make the function fit the curve better.

A Genetic Algorithm (GA) is just a tool to reduce the search space. For instance
if you had 5 indicators with a total of 10 possible parameters, then to try every
possible combination would take a long time. Trying every possibility is a brute force
method and isn't practical unless your model is extremely simple.

A GA looks at the problem differently. If we wanted to find the highest peak in a range of mountains, then visiting every mountain takes too long, so a GA
uses a targetted approach. I.E. You guess a local peak to begin with. It probably
isn't the highest peak, so you guess again. Then using a chromosomelgene
model borrowed from biology, where you have survival of the fittest, you match the good parameters of the mountains and keep going. Essentially you keep going, at every generation, the fittest members survive to keep going, until you can make no more "reasonable" improvement. I.E. Your solution evolves to find the
best answer
just like life on earth. What's happening is your taking spot readings over the range
and homing in on the highest mountain.

A GA has a fitness function (in this case the height of the mountain), in the case of
trading, it's your goal. The GA is a tool to help us fit the curve. A brute force method can be better than a GA, but if a GA doesn't reach the correct answer, it will likely
reach one that's close. I.E. In the trade off between brute force and a GA, GA is
really only the practical way to go, although brute force may be occasionally a little
more superior in result.

So lets try some examples of incorrectly curve fitting with a few examples.

CURVE FITTING WITH TOO LITTLE DATA:

So we toss some coins. Coins can be heads or tails and our goal is to build a perfect
coin toss predictor. We toss 3 times, and get heads each time. Therefore we
optimize our solution, and build a perfect coin tosser that always generates heads
as the answer. So what's wrong?

Well, our curve is heads/tails, but we took such a small sample (of size 3), that
we didn't see the real picture. I.E. We tried to fit a curve where we couldn't see the whole curve. In trading, this is a classic mistake that is commonly made. We genetically optimize with not enough data. Remember from before that to be
reasonably confident that we haven't incorrectly curve fitted the data, we need
30 trades per degree of freedom (DOF) for every variable in the model.

This shows up as, building a model that optimizes well, then trades poorly in real time.
If you tested with adequate data, you'd have found out that it really was poor in the
first place.

CURVE FITTING BY SELECTION: STOCK PICKING

We can also incorrectly curve fit by picking results, without even using a GA.

For instance, if you were to trade say 10 stocks randomly for a period of time,
you'd likely make money on some and lose money on others. Just like tossing
a coin would produce heads and tails.

So you have your perfect model and you want to trade, but it works on some stocks
not others, so you plug in 100 stocks to find out which ones do well and which ones
do poorly, and keep the good ones. Well you've just incorrectly curve fitted by
another means. (or another way of looking at it is rendered your out of sample to be in sample). This is because out of any population (the 100), if you pick and choose your sample (the good ones), then your sample is no longer truely representative of your population.

CURVE FITTING BY SELECTION: INDICATORS

So, instead of picking the best stocks to use in your model, you pick the best indicators, i.e. just keep plugging at it until you find indicators that work.
Again, just another form of incorrect curve fitting for the same reason as the
last.

CURVE FITTING BY SELECTION: PICKING THE BEST RESULTS

So you keep trying models until you find the best one. Again, just incorrectly curve fitting.

As you can see, this is a huge problem, there are so many ways to incorrectly
curve fit. Anywhere where you pick and choose, or try different things open you
up to curve fitting.

One solution might be to create another out of sample testing to get around the problem. But again, if you pick and choose between those out of samples, you're
opening yourself up to the same problem again.

So, incorrectly curve fitting is not 100% avoidable, but needs to be realized and
managed. Personally I follow this method to avoid it as much as possible:

1. Never try things out in a model in an untargetted approach, and
this is where these threads about design models come into the picture. Start off
with a goal, and design a model to fit that goal, don't just guess at methods or
indicators that will work, start off with solid design from the ground up.

2. Use a GA to improve good models, not to make bad models work.

3. If using a GA, use it at the end of the process, i.e. as a final improvement to an
already good model.

4. Use sufficient data to test with.

5. Always keep additional out of samples to test on. A good out of sample is
always paper trading.

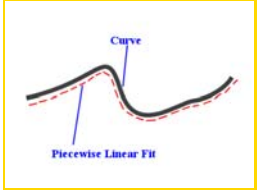
6. Never pick and choose results, stocks or anything else. (At least not without
being aware of it and knowing the effect).

7. Keep degrees of freedom low. I.E. The smaller the DOF, the less data you
need to validate which makes everything a lot simpler to test.

USING CURVE FITTING TO ADVANTAGE:

There is another way to approach curve fitting and make it work to your advantage. At first it seems like a crazy approach, but there are good reasons why it works. That is to keep DOF small and optimize frequently.

The reason for this is because of the curve fitting. Normally we wish to fit that curve perfectly, however, any curve can be approximated by a series of small lines. This is
called a Piecewise Linear Approach. Linear = Line, Piecewise means small pieces.



I.E. If you keep Degrees Of Freedom (DOF) low so that your fit can be validated in minimal time, i.e. you're creating a small line, then it can fit (approximately) the curve
of your function for a small period of time. You then reoptimize frequently to get additional small segments of lines.

Re: Curve fitting. What it is, how to avoid it and how to use it to advantage

Date :11/10/2005 9:21:15 AM Poster : Dan

Mark,

I've been working on some models using the 30 trades per DOF guideline, and am beginning to see some possibilities emerge. However, I am hitting a particular snag consistently, and I wonder if you (or the Ward folks) have any insight/suggestions. It seems like the number of trades I need to validate a model demands

about 5 yrs. of testing; the resulting equity curve (while profitable overall) is consistently flat toward the right edge of the chart, where I need to start trading.

For example, let's take a simple 2 indicator crossover system (I am using some add-on indicators). I optimize 2 indicators for longs, and 2 indicators for shorts. (I like for values for longs and shorts to be different b/c the market accelerates downward more quickly than upward.) This equals 4 variables, therefore the model would need 120 trades to validate. In addition, I like to use an exit indicator, which sometimes I will optimize as linked for longs/shorts. This brings the minimum no. of trades up to 150-180 depending on whether the exit variables for long/shorts are linked or not.

I find that I need to go about 5 yrs. back in order for the model to accumulate that many trades. No matter what objective I use to optimize the equity curve (max return * equity curve corr. is my favorite), the GA seems to produce results that are great in the first 3 yrs or so, but, again, mostly flat for the last year or so.

Any suggestions/ideas? Is there any way to ask the GA to steepen the curve toward the end of the model, or valid shortcuts around the 30 trades per DOF guideline?

Many thanks for your kind attention--

Dan Melton

Hi Dan,

DOF means a lot of different things to different people, however the way I approach
it is as follows.

To me a degree of freedom is an item that can change in a model. This could be:
1. A parameter to an indicator
2. Choice of indicator
3. Choice of security

All this is pretty vague, so hopefully the following examples will clarify it:

Model Inputs: RSI(x) on 1 security where x is optimized.
Answer: 1 DOF as x is a variable parameter i.e. it can change.

Model Inputs: RSI(5) on 1 security.
Answer: 1 DOF (as you need to validate the model on something).

Model Inputs: MACD(close,12,26) on 1 security
Answer: 1 DOF (as you need to validate the model on something).

Model Inputs: MACD(close,x,y) on 1 security where x/y are optimized.
Answer: 2 DOF (x and y)

Model Inputs: MACD(RSI (z), x, y) on 1 security where z/x/y are optimized.
Answer: 3 DOF (x, y and z)

Model Inputs: MACD (RSI (z), x, y) where z/x/y are optimized, and then we try
different stocks against it to find which ones perform best.
Answer: 4 DOF (x,y,z and stock selection)

Model Inputs: Indicator(x) where x is optimized, and we try many different indicators
to find one that works on 1 security.
Answer: 2 DOF (x and Indicator selection)

Model Inputs: MACD(close,5,20) where we just guessed 5,20 as being the parameters
on 1 security.
Answer: 1 DOF (as you need to validate the model on something)

Model Inputs: MACD(close,5,20) however, we tried many different values for 5 and 20 until we found the ones that worked on 1 security.
Answer: 2 DOF (becuase you were manually changing both the 5 and 20).

So if you let the optimizer choose a value, 1 DOF gets added. If you
manually choose a value through experimentation, 1 DOF gets added.

>Many thanks for your kind attention--

>Dan Melton

It's difficult to provide exact reasons without seeing the model, however these are some points:

1. You mention that the equity curve is good at the beginning and flat at the end. That suggests that you're running the GA on a certain period of time, and your "out of sample" is recent (presumably the flat part). A GA will generally do a good job of curve fitting because that's what it's designed to do. So the "out of sample" (provided you haven't curve fitted by manually curve fitting, i.e. stock selection etc.) becomes the measurement of how well your model is working.
I.E. If you've validated with enough trades for the DOF and the out of sample is poor, then the model more than likely doesn't work, and the model needs refining or replacing.

The GA always tries to fit over the data you provide it, i.e. if you use the GA over 8 years, then the results should be fairly consistant during that time (provided the market has the opportunity to make money). Which is why you need the out of sample to validate it.

2. Regarding DOF, you can't really cheat as such. However you can make better indicators that have fewer DOF. It's feasible to build an indicator (assuming the 2 indicators you are using are the same in the short and long), such that you have 2 indicators for long and short with a 3rd variable which essentially determines essentially becomes the adaption between short and long, that would give you 3 DOF and save 1 DOF, as currently you have duplication of information, essentially you're removing correlated information by removing that 1 DOF.

If you can get DOF really low, i.e. 1 DOF (maybe 2), then you can get into piecewise linear approach of curve fitting (you still need to at least validate on an out of sample, until you're happy the model works).

3. Also watch out for lag. I get the impression (although you don't explicitly say), that you're using lagging indicators.

If possible, post your model to the forum, and we can take a further look at it.

Hi Dan,

DOF means a lot of different things to different people, however the way I approach it is as follows.

To me a degree of freedom is an item that can change in a model. This could be:
1. A parameter to an indicator
2. Choice of indicator
3. Choice of security

All this is pretty vague, so hopefully the following examples will clarify it:

Model Inputs: RSI(x) on 1 security where x is optimized.
Answer: 1 DOF as x is a variable parameter i.e. it can change.

Model Inputs: RSI(5) on 1 security.
Answer: 1 DOF (as you need to validate the model on something).

Model Inputs: MACD(close,12,26) on 1 security
Answer: 1 DOF (as you need to validate the model on something).

Model Inputs: MACD(close,x,y) on 1 security where x/y are optimized.
Answer: 2 DOF (x and y)

Model Inputs: MACD(RSI (z), x, y) on 1 security where z/x/y are optimized.
Answer: 3 DOF (x, y and z)

Model Inputs: MACD (RSI (z), x, y) where z/x/y are optimized, and then we try
different stocks against it to find which ones perform best.
Answer: 4 DOF (x,y,z and stock selection)

Model Inputs: Indicator(x) where x is optimized, and we try many different indicators
to find one that works on 1 security.
Answer: 2 DOF (x and Indicator selection)

Model Inputs: MACD(close,5,20) where we just guessed 5,20 as being the parameters
on 1 security.
Answer: 1 DOF (as you need to validate the model on something)

Model Inputs: MACD(close,5,20) however, we tried many different values for 5 and 20 until we found the ones that worked on 1 security.
Answer: 2 DOF (because you were manually changing both the 5 and 20).

So if you let the optimizer choose a value, 1 DOF gets added. If you
manually choose a value through experimentation, 1 DOF gets added.

A GA has a fitness function (in this case the height of the mountain), in the case of
trading, it's your goal. The GA is a tool to help us fit the curve. A brute force method can be better than a GA, but if a GA doesn't reach the correct answer, it will likely reach one that's close. I.E. In the trade off between brute force and a GA, GA is
really only the practical way to go, although brute force may be occasionally a little

more superior in result.

So lets try some examples of incorrectly curve fitting with a few examples.

CURVE FITTING WITH TOO LITTLE DATA:

So we toss some coins. Coins can be heads or tails and our goal is to build a perfect coin toss predictor. We toss 3 times, and get heads each time. Therefore we optimize our solution, and build a perfect coin tosser that always generates heads as the answer. So what's wrong?

Well, our curve is heads/tails, but we took such a small sample (of size 3), that we didn't see the real picture. I.E. We tried to fit a curve where we couldn't see the whole curve. In trading, this is a classic mistake that is commonly made. We genetically optimize with not enough data. Remember from before that to be reasonably confident that we haven't incorrectly curve fitted the data, we need 30 trades per degree of freedom (DOF) for every variable in the model.

This shows up as, building a model that optimizes well, then trades poorly in real time. If you tested with adequate data, you'd have found out that it really was poor in the first place.

CURVE FITTING BY SELECTION: STOCK PICKING

We can also incorrectly curve fit by picking results, without even using a GA.

For instance, if you were to trade say 10 stocks randomly for a period of time, you'd likely make money on some and lose money on others. Just like tossing a coin would produce heads and tails.

So you have your perfect model and you want to trade, but it works on some stocks not others, so you plug in 100 stocks to find out which ones do well and which ones do poorly, and keep the good ones. Well you've just incorrectly curve fitted by another means. (or another way of looking at it is rendered your out of sample to be in sample). This is because out of any population (the 100), if you pick and choose your sample (the good ones), then your sample is no longer truely representative of your population.

CURVE FITTING BY SELECTION: INDICATORS

So, instead of picking the best stocks to use in your model, you pick the best indicators, i.e. just keep plugging at it until you find indicators that work. Again, just another form of incorrect curve fitting for the same reason as the last.

CURVE FITTING BY SELECTION: PICKING THE BEST RESULTS

So you keep trying models until you find the best one. Again, just incorrectly curve fitting.

As you can see, this is a huge problem, there are so many ways to incorrectly curve fit. Anywhere where you pick and choose, or try different things open you up to curve fitting.

One solution might be to create another out of sample testing to get around the problem. But again, if you pick and choose between those out of samples, you're opening yourself up to the same problem again.

So, incorrectly curve fitting is not 100% avoidable, but needs to be realized and managed. Personally I follow this method to avoid it as much as possible:

1. Never try things out in a model in an untargetted approach, and this is where these threads about design models come into the picture. Start off with a goal, and design a model to fit that goal, don't just guess at methods or indicators that will work, start off with solid design from the ground up.

2. Use a GA to improve good models, not to make bad models work.

3. If using a GA, use it at the end of the process, i.e. as a final improvement to an already good model.

4. Use sufficient data to test with.

5. Always keep additional out of samples to test on. A good out of sample is always paper trading.

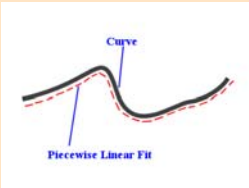
6. Never pick and choose results, stocks or anything else. (At least not without being aware of it and knowing the effect).

7. Keep degrees of freedom low. I.E. The smaller the DOF, the less data you need to validate which makes everything a lot simpler to test.

USING CURVE FITTING TO ADVANTAGE:

There is another way to approach curve fitting and make it work to your advantage. At first it seems like a crazy approach, but there are good reasons why it works. That is to keep DOF small and optimize frequently.

The reason for this is because of the curve fitting. Normally we wish to fit that curve perfectly, however, any curve can be approximated by a series of small lines. This is called a Piecewise Linear Approach. Linear = Line, Piecewise means small pieces.



I.E. If you keep Degrees Of Freedom (DOF) low so that your fit can be validated in minimal time, i.e. you're creating a small line, then it can fit (approximately) the curve of your function for a small period of time. You then reoptimize frequently to get additional small segments of lines.

Re: Curve fitting. What it is, how to avoid it and how to use it to advantage

Date :11/15/2005 11:05:45 AM Poster : Dan

Mark,

I'm attaching an example chart--a simple out-of-the-box crossover system from the Cybernetic Indicator add-on using Adaptive RVI. From here I sometimes elaborate with alternative exits and/or stops (results roughly similar). I'd also like to combine this with another system that kicks in when the market is trending as opposed to range-bound, but here is where I get into trouble in needing so many trades to account for the DOF for what is essentially two systems combined into one.

In case you don't have those indicators on your machine, I'm attaching a picture also (at least you can see the equity curve).

Thanks for any other thoughts you might have!

It's difficult to provide exact reasons without seeing the model, however these are some
points:

1. You mention that the equity curve is good at the beginning and flat at the end. That suggests
that you're running the GA on a certain period of time, and your "out of sample" is recent (presumably the flat part). A GA will generally do a good job of curve fitting because that's what it's designed to do. So the "out of sample" (provided you haven't curve fitted by manually curve fitting, i.e. stock selection etc.) becomes the measurement of how well your model is working.
I.E. If you've validated with enough trades for the DOF and the out of sample is poor, then the model more than likely doesn't work, and the model needs refining or replacing.

The GA always tries to fit over the data you provide it, i.e. if you use the GA over 8 years, then
the results should be fairly consistant during that time (provided the market has the opportunity to make money). Which is why you need the out of sample to validate it.

2. Regarding DOF, you can't really cheat as such. However you can make better indicators that
have fewer DOF. It's feasible to build an indicator (assuming the 2 indicators you are using are the same in the short and long), such that you have 2 indicators for long and short with a 3rd variable which essentially determines essentially becomes the adaption between short and long, that would give you 3 DOF and save 1 DOF, as currently you have duplication of information, essentially you're removing correlated information by removing that 1 DOF.

If you can get DOF really low, i.e. 1 DOF (maybe 2), then you can get into piecewise linear approach of curve fitting (you still need to at least validate on an out of sample, until you're happy the model works).

3. Also watch out for lag. I get the impression (although you don't explicitly say), that you're
using lagging indicators.

If possible, post your model to the forum, and we can take a further look at it.

Hi Dan,

DOF means a lot of different things to different people, however the way I approach
it is as follows.

To me a degree of freedom is an item that can change in a model. This could be:
1. A parameter to an indicator
2. Choice of indicator
3. Choice of security

All this is pretty vague, so hopefully the following examples will clarify it:

Model Inputs: RSI(x) on 1 security where x is optimized.
Answer: 1 DOF as x is a variable parameter i.e. it can change.

Model Inputs: RSI(5) on 1 security.
Answer: 1 DOF (as you need to validate the model on something).

Model Inputs: MACD(close,12,26) on 1 security
Answer: 1 DOF (as you need to validate the model on something).

Model Inputs: MACD(close,x,y) on 1 security where x/y are optimized.
Answer: 2 DOF (x and y)

Model Inputs: MACD(RSI (z), x, y) on 1 security where z/x/y are optimized.
Answer: 3 DOF (x, y and z)

Model Inputs: MACD (RSI (z), x, y) where z/x/y are optimized, and then we try
different stocks against it to find which ones perform best.
Answer: 4 DOF (x,y,z and stock selection)

Model Inputs: Indicator(x) where x is optimized, and we try many different indicators
to find one that works on 1 security.
Answer: 2 DOF (x and Indicator selection)

Model Inputs: MACD(close,5,20) where we just guessed 5,20 as being the parameters
on 1 security.
Answer: 1 DOF (as you need to validate the model on something)

Model Inputs: MACD(close,5,20) however, we tried many different values for 5 and 20 until we found the ones that worked on 1 security.
Answer: 2 DOF (becuase you were manually changing both the 5 and 20).

So if you let the optimizer choose a value, 1 DOF gets added. If you
manually choose a value through experimentation, 1 DOF gets added.

This thread is about curve fitting. I also refer you to Steve Ward's tips on preventing
over-optimization http://www.ward.net/cgi-bin/viewtip.asp?ID=105 as a guideline for
what you can do to avoid it.

So, lets start off with what a GA (Genetic Algorithm) is, to remove some of the mysticism behind the GA built into Neuroshell. Personally I believe that it's
by understanding the principles of this that it can be better used to advantage.
The GA is a very powerful tool if used correctly, if used incorrectly it can sink
you.

You've probably come across the following problem, you build your
system, keep optimizing various types of system until you find one that does well,
then you trade it in realtime, and poof, that well performing system eats you alive.
If you've done everything else correctly, i.e. tested on out samples and used walk forwards, then the chances are you've just incorrectly curve fitted without realizing it.

So what is curve fitting? If you imagine your trading system like this, you
have inputs and you have an output (trading signals). You have a black box in the middle which translates between. Essentially the output is a function
of the input. I.E. Output=f (Input1..Input N)

The output is the curve, i.e. it's a varying function, and the idea is that we have to
design the function so that it fits that curve.

So, lets translate this to the NST world. We use a bunch of indicators to go into
our "function", and then see how well the function works (performance). However
it doesn't do too well, so we use the optimization feature in NST (a GA) to alter
the parameters to the indicators to make the function fit the curve better.

A Genetic Algorithm (GA) is just a tool to reduce the search space. For instance
if you had 5 indicators with a total of 10 possible parameters, then to try every
possible combination would take a long time. Trying every possibility is a brute force
method and isn't practical unless your model is extremely simple.

A GA looks at the problem differently. If we wanted to find the highest peak in a range of mountains, then visiting every mountain takes too long, so a GA
uses a targetted approach. I.E. You guess a local peak to begin with. It probably
isn't the highest peak, so you guess again. Then using a chromosome/gene
model borrowed from biology, where you have survival of the fittest, you match the good parameters of the mountains and keep going. Essentially you keep going, at every generation, the fittest members survive to keep going, until you can make no more "reasonable" improvement. I.E. Your solution evolves to find the best answer
just like life on earth. What's happening is your taking spot readings over the range
and homing in on the highest mountain.

A GA has a fitness function (in this case the height of the mountain), in the case of
trading, it's your goal. The GA is a tool to help us fit the curve. A brute force method can be better than a GA, but if a GA doesn't reach the correct answer, it will likely
reach one that's close. I.E. In the trade off between brute force and a GA, GA is
really only the practical way to go, although brute force may be occasionally a little
more superior in result.

So lets try some examples of incorrectly curve fitting with a few examples.

CURVE FITTING WITH TOO LITTLE DATA:

So we toss some coins. Coins can be heads or tails and our goal is to build a perfect
coin toss predictor. We toss 3 times, and get heads each time. Therefore we
optimize our solution, and build a perfect coin tosser that always generates heads
as the answer. So what's wrong?

Well, our curve is heads/tails, but we took such a small sample (of size 3), that
we didn't see the real picture. I.E. We tried to fit a curve where we couldn't see the whole curve. In trading, this is a classic mistake that is commonly made. We genetically optimize with not enough data. Remember from before that to be
reasonably confident that we haven't incorrectly curve fitted the data, we need
30 trades per degree of freedom (DOF) for every variable in the model.

This shows up as, building a model that optimizes well, then trades poorly in real time.
If you tested with adequate data, you'd have found out that it really was poor in the
first place.

CURVE FITTING BY SELECTION: STOCK PICKING

We can also incorrectly curve fit by picking results, without even using a GA.

For instance, if you were to trade say 10 stocks randomly for a period of time,
you'd likely make money on some and lose money on others. Just like tossing
a coin would produce heads and tails.

So you have your perfect model and you want to trade, but it works on some stocks
not others, so you plug in 100 stocks to find out which ones do well and which ones
do poorly, and keep the good ones. Well you've just incorrectly curve fitted by
another means. (or another way of looking at it is rendered your out of sample to be in sample). This is because out of any population (the 100), if you pick and choose your sample (the good ones), then your sample is no longer truely representative of your population.

CURVE FITTING BY SELECTION: INDICATORS

So, instead of picking the best stocks to use in your model, you pick the best indicators. i.e. just keep plugging at it until you find indicators that work.
Again, just another form of incorrect curve fitting for the same reason as the
last.

CURVE FITTING BY SELECTION: PICKING THE BEST RESULTS

So you keep trying models until you find the best one. Again, just incorrectly curve fitting.

As you can see, this is a huge problem, there are so many ways to incorrectly
curve fit. Anywhere where you pick and choose, or try different things open you
up to curve fitting.

One solution might be to create another out of sample testing to get around the problem. But again, if you pick and choose between those out of samples, you're
opening yourself up to the same problem again.

So, incorrectly curve fitting is not 100% avoidable, but needs to be realized and

managed. Personally I follow this method to avoid it as much as possible:

1. Never try things out in a model in an untargetted approach, and
this is where these threads about design models come into the picture. Start off

Re: Curve fitting, What it is, how to avoid it and how to use it to advantage

Date :11/20/2005 3:00:07 PM Poster : Mark Simpson

Hi Dan,

First of all, you're not using an out of sample test as such, because the optimization date range is the same as the paper trading date range. Though this isn't causing the flat
spot, it doesn't provide validation of the model either. I.E. you're validating the performance of the model with exactly the same data you're curve fitting the model to work best with. In NST you can seperate out the paper trading date range from the optimization range. However
when you do that, you'll see the model doesn't perform
too well anymore.

Regarding the flat spot. As Steve said, the market dynamics have changed. If
you put a volatility indicator on that same chart, you'll see that around the beginning of 2003, volatility significantly dropped. The model worked well in a high volatility situation but not in a low volatility situation. Unfortunately, the DOF issue precludes you from
producing a new model yet, i.e. you don't have enough recent data.

Assuming the model did successfully validate in paper trading at some point in time,
then the only other way around the change in market this would be to normalize time,
i.e. change the underlying data, this would produce volatility which was consistant and indicators which were "better behaved".

Hi Dan,

DOF means a lot of different things to different people, however the way I approach
it is as follows.

To me a degree of freedom is an item that can change in a model. This could be:
1. A parameter to an indicator
2. Choice of indicator
3. Choice of security

All this is pretty vague, so hopefully the following examples will clarify it:

Model Inputs: RSI(x) on 1 security where x is optimized.
Answer: 1 DOF as x is a variable parameter i.e. it can change.

Model Inputs: RSI(5) on 1 security.
Answer: 1 DOF (as you need to validate the model on something).

Model Inputs: MACD(close,12,26) on 1 security
Answer: 1 DOF (as you need to validate the model on something).

Model Inputs: MACD(close,x,y) on 1 security where x/y are optimized.
Answer: 2 DOF (x and y)

Model Inputs: MACD(RSI (z), x, y) on 1 security where z/x/y are optimized.
Answer: 3 DOF (x, y and z)

Model Inputs: MACD (RSI (z), x, y) where z/x/y are optimized, and then we try
different stocks against it to find which ones perform best.
Answer: 4 DOF (x,y,z and stock selection)

Model Inputs: Indicator(x) where x is optimized, and we try many different indicators
to find one that works on 1 security.
Answer: 2 DOF (x and Indicator selection)

Model Inputs: MACD(close,5,20) where we just guessed 5,20 as being the parameters
on 1 security.
Answer: 1 DOF (as you need to validate the model on something)

Model Inputs: MACD(close,5,20) however, we tried many different values for 5 and 20 until we found the ones that worked on 1 security.
Answer: 2 DOF (becuase you were manually changing both the 5 and 20).

So if you let the optimizer choose a value, 1 DOF gets added. If you
manually choose a value through experimentation, 1 DOF gets added.

really only the practical way to go, although brute force may be occasionally a little
more superior in result.

So lets try some examples of incorrectly curve fitting with a few examples.

CURVE FITTING WITH TOO LITTLE DATA:

So we toss some coins. Coins can be heads or tails and our goal is to build a perfect
coin toss predictor. We toss 3 times, and get heads each time. Therefore we
optimize our solution, and build a perfect coin tosser that always generates heads
as the answer. So what's wrong?

Well, our curve is heads/tails, but we took such a small sample (of size 3), that
we didn't see the real picture. I.E. We tried to fit a curve where we couldn't see the whole curve. In trading, this is a classic mistake that is commonly made. We genetically optimize with not enough data. Remember from before that to be
reasonably confident that we haven't incorrectly curve fitted the data, we need
30 trades per degree of freedom (DOF) for every variable in the model.

This shows up as, building a model that optimizes well, then trades poorly in real time.
If you tested with adequate data, you'd have found out that it really was poor in the
first place.

CURVE FITTING BY SELECTION: STOCK PICKING

We can also incorrectly curve fit by picking results, without even using a GA.

For instance, if you were to trade say 10 stocks randomly for a period of time,
you'd likely make money on some and lose money on others. Just like tossing
a coin would produce heads and tails.

So you have your perfect model and you want to trade, but it works on some stocks
not others, so you plug in 100 stocks to find out which ones do well and which ones
do poorly, and keep the good ones. Well you've just incorrectly curve fitted by
another means. (or another way of looking at it is rendered your out of sample to be in sample). This is because out of any population (the 100), if you pick and choose your sample (the good ones), then your sample is no longer truely representative of your population.

CURVE FITTING BY SELECTION: INDICATORS

So, instead of picking the best stocks to use in your model, you pick the best indicators, i.e. just keep plugging at it until you find indicators that work.
Again, just another form of incorrect curve fitting for the same reason as the
last.

CURVE FITTING BY SELECTION: PICKING THE BEST RESULTS

So you keep trying models until you find the best one. Again, just incorrectly curve fitting.

As you can see, this is a huge problem, there are so many ways to incorrectly
curve fit. Anywhere where you pick and choose, or try different things open you
up to curve fitting.

One solution might be to create another out of sample testing to get around the problem. But again, if you pick and choose between those out of samples, you're
opening yourself up to the same problem again.

So, incorrectly curve fitting is not 100% avoidable, but needs to be realized and
managed. Personally I follow this method to avoid it as much as possible:

1. Never try things out in a model in an untargetted approach, and
this is where these threads about design models come into the picture. Start off
with a goal, and design a model to fit that goal, don't just guess at methods or
indicators that will work, start off with solid design from the ground up.

2. Use a GA to improve good models, not to make bad models work.

3. If using a GA, use it at the end of the process, i.e. as a final improvement to an
already good model.

4. Use sufficient data to test with.

5. Always keep additional out of samples to test on. A good out of sample is
always paper trading.

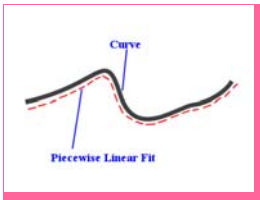
6. Never pick and choose results, stocks or anything else. (At least not without
being aware of it and knowing the effect).

7. Keep degrees of freedom low. I.E. The smaller the DOF, the less data you
need to validate which makes everything a lot simpler to test.

USING CURVE FITTING TO ADVANTAGE:

There is another way to approach curve fitting and make it work to your advantage. At first it seems like a crazy approach, but there are good reasons why it works. That is to keep DOF small and optimize frequently.

The reason for this is because of the curve fitting. Normally we wish to fit that curve perfectly, however, any curve can be approximated by a series of small lines. This is
called a Piecewise Linear Approach. Linear = Line, Piecewise means small pieces.



I.E. If you keep Degrees Of Freedom (DOF) low so that your fit can be validated in minimal time, i.e. you're creating a small line, then it can fit (approximately) the curve of your function for a small period of time. You then reoptimize frequently to get additional small segments of lines.

Re: Curve fitting. What it is, how to avoid it and how to use it to advantage

Date :11/22/2005 12:39:52 PM Poster : Steve Eberbach

Hi Mark: It is for this reason (changing volatility) that I have always converted all my indicators into moving z-score plus standard deviation (two variables). That way I have the inputs I need to test if there is useful information in the changes of volatility of each input. Another benefit of z-score is that the numeric indicators are nicely normalized, making it easier for me to read all my charts, since then I can put several indicators of different colors on one chart without severe vertical axis scaling problems which arise when trying to draw comparative charts.

Since Steve has written normalization into the neural nets, maybe he could include an option to simply display the input indicators as normalized for the prediction wizard, wherever these are in the memory, whether it is plus-minus a range, or z-score, or something else.

On 11/20/2005 3:00:07 PM Mark Simpson wrote:
Hi Dan,

First of all, you're not using an out of sample test as such, because the optimization date range is the same as the paper trading date range. Though this isn't causing the flat spot, it doesn't provide validation of the model either. I.E. you're validating the performance of the model with exactly the same data you're curve fitting the model to work best with. In NST you can seperate out the paper trading date range from the optimization range. However when you do that, you'll see the model doesn't perform too well anymore.

Regarding the flat spot. As Steve said, the market dynamics have changed. If you put a volatility indicator on that same chart, you'll see that around the beginning of 2003, volatility significantly dropped. The model worked well in a high volatility situation but not in a low volatility situation. Unfortunately, the DOF issue precludes you from producing a new model yet, i.e. you don't have enough recent data.

Assuming the model did successfully validate in paper trading at some point in time, then the only other way around the change in market this would be to normalize time, i.e. change the underlying data, this would produce volatility which was consistant and indicators which were "better behaved".

>Dan Melton

It's difficult to provide exact reasons without seeing the model, however these are some points:

1. You mention that the equity curve is good at the beginning and flat at the end. That suggests that you're running the GA on a certain period of time, and your "out of sample" is recent (presumably the flat part). A GA will generally do a good job of curve fitting because that's what it's designed to do. So the "out of sample" (provided you haven't curve fitted by manually curve fitting, i.e. stock selection etc.) becomes the measurement of how well your model is working.
I.E. If you've validated with enough trades for the DOF and the out of sample is poor, then the model more than likely doesn't work, and the model needs refining or replacing.

The GA always tries to fit over the data you provide it, i.e. if you use the GA over 8 years, then the results should be fairly consistant during that time (provided the market has the opportunity to make money). Which is why you need the out of sample to validate it.

2. Regarding DOF, you can't really cheat as such. However you can make better indicators that have fewer DOF. It's feasible to build an indicator (assuming the 2 indicators you are using are the same in the short and long), such that you have 2 indicators for long and short with a 3rd variable which essentially determines essentially becomes the adaption between short and long, that would give you 3 DOF and save 1 DOF, as currently you have duplication of information, essentially you're removing correlated information by removing that 1 DOF.

If you can get DOF really low, i.e. 1 DOF (maybe 2), then you can get into piecewise linear approach of curve fitting (you still need to at least validate on an out of sample, until you're happy the model works).

3. Also watch out for lag. I get the impression (although you don't explicitly say), that you're using lagging indicators.

If possible, post your model to the forum, and we can take a further look at it.

Hi Dan,

DOF means a lot of different things to different people, however the way I approach it is as follows.

To me a degree of freedom is an item that can change in a model. This could be:
1. A parameter to an indicator
2. Choice of indicator
3. Choice of security

All this is pretty vague, so hopefully the following examples will clarify it:

Model Inputs: RSI(x) on 1 security where x is optimized.
Answer: 1 DOF as x is a variable parameter i.e. it can change.

Model Inputs: RSI(5) on 1 security.
Answer: 1 DOF (as you need to validate the model on something).

Model Inputs: MACD(close,12,26) on 1 security
Answer: 1 DOF (as you need to validate the model on something).

Model Inputs: MACD(close,x,y) on 1 security where x/y are optimized.
Answer: 2 DOF (x and y)

Model Inputs: MACD(RSI (z), x, y) on 1 security where z/x/y are optimized.
Answer: 3 DOF (x, y and z)

Model Inputs: MACD (RSI (z), x, y) where z/x/y are optimized, and then we try different stocks against it to find which ones perform best.
Answer: 4 DOF (x,y,z and stock selection)

Model Inputs: Indicator(x) where x is optimized, and we try many different indicators to find one that works on 1 security.
Answer: 2 DOF (x and Indicator selection)

Model Inputs: MACD(close,5,20) where we just guessed 5,20 as being the parameters on 1 security.
Answer: 1 DOF (as you need to validate the model on something)

Model Inputs: MACD(close,5,20) however, we tried many different values for 5 and 20 until we found the ones that worked on 1 security.
Answer: 2 DOF (becuase you were manually changing both the 5 and 20).

So if you let the optimizer choose a value, 1 DOF gets added. If you manually choose a value through experimentation, 1 DOF gets added.

This thread is about curve fitting. I also refer you to Steve Ward's tips on preventing over-optimization http://www.ward.net/cgi-bin/viewtip.asp?ID=105 as a guideline for what you can do to avoid it.

So, lets start off with what a GA (Genetic Algorithm) is, to remove some of the mysticism behind the GA built into Neuroshell. Personally I believe that it's by understanding the principles of this that it can be better used to advantage.
The GA is a very powerful tool if used correctly, if used incorrectly it can sink you.

You've probably come across the following problem, you build your system, keep optimizing various types of system until you find one that does well, then you trade it in realtime, and poof, that well performing system eats you alive.
If you've done everything else correctly, i.e. tested on out samples and used walk forwards, then the chances are you've just incorrectly curve fitted without realizing it.

So what is curve fitting? If you imagine your trading system like this, you have inputs and you have an output (trading signals). You have a black box in the middle which translates between. Essentially the output is a function of the input. I.E. Output=f (Input1..Input N)

The output is the curve, i.e. it's a varying function, and the idea is that we have to design the function so that it fits that curve.

So, lets translate this to the NST world. We use a bunch of indicators to go into our "function", and then see how well the function works (performance). However it doesn't do too well, so we use the optimization feature in NST (a GA) to alter the parameters to the indicators to make the function fit the curve better.

A Genetic Algorithm (GA) is just a tool to reduce the search space. For instance if you had 5 indicators with a total of 10 possible parameters, then to try every possible combination would take a long time. Trying every possibility is a brute force method and isn't practical unless your model is extremely simple.

A GA looks at the problem differently. If we wanted to find the highest peak in a range of mountains, then visiting every mountain takes too long, so a GA uses a targetted approach. I.E. You guess a local peak to begin with. It probably isn't the highest peak, so you guess again. Then using a chromosome/gene model borrowed from biology, where you have survival of the fittest, you match the good parameters of the mountains and keep going. Essentially you keep going, at every generation, the fittest members survive to keep going, until you can make no more "reasonable" improvement. I.E. Your solution evolves to find the best answer just like life on earth. What's happening is your taking spot readings over the range and homing in on the highest mountain.

A GA has a fitness function (in this case the height of the mountain), in the case of trading, it's your goal. The GA is a tool to help us fit the curve. A brute force method can be better than a GA, but if a GA doesn't reach the correct answer, it will likely reach one that's close. I.E. In the trade off between brute force and a GA, GA is really only the practical way to go, although brute force may be occasionally a little more superior in result.

So lets try some examples of incorrectly curve fitting with a few examples.

CURVE FITTING WITH TOO LITTLE DATA:

So we toss some coins. Coins can be heads or tails and our goal is to build a perfect coin toss predictor. We toss 3 times, and get heads each time. Therefore we optimize our solution, and build a perfect coin tosser that always generates heads as the answer. So what's wrong?

Well, our curve is heads/tails, but we took such a small sample (of size 3), that we didn't see the real picture. I.E. We tried to fit a curve where we couldn't see the whole curve. In trading, this is a classic mistake that is commonly made. We genetically optimize with not enough data. Remember from before that to be reasonably confident that we haven't incorrectly curve fitted the data, we need 30 trades per degree of freedom (DOF) for every variable in the model.

This shows up as, building a model that optimizes well, then trades poorly in real time.
If you tested with adequate data, you'd have found out that it really was poor in the first place.

CURVE FITTING BY SELECTION: STOCK PICKING

We can also incorrectly curve fit by picking results, without even using a GA.

For instance, if you were to trade say 10 stocks randomly for a period of time, you'd likely make money on some and lose money on others. Just like tossing a coin would produce heads and tails.

So you have your perfect model and you want to trade, but it works on some stocks not others, so you plug in 100 stocks to find out which ones do well and which ones do poorly, and keep the good ones. Well you've just incorrectly curve fitted by another means. (or another way of looking at it is rendered your out of sample to be in sample). This is because out of any population (the 100), if you pick and choose your sample (the good ones), then your sample is no longer truely representative of your population.

CURVE FITTING BY SELECTION: INDICATORS

So, instead of picking the best stocks to use in your model, you pick the best indicators, i.e. just keep plugging at it until you find indicators that work.
Again, just another form of incorrect curve fitting for the same reason as the last.

CURVE FITTING BY SELECTION: PICKING THE BEST RESULTS

So you keep trying models until you find the best one. Again, just incorrectly curve fitting.

As you can see, this is a huge problem, there are so many ways to incorrectly curve fit. Anywhere where you pick and choose, or try different things open you up to curve fitting.

Date :11/25/2005 2:12:37 PM Poster : Sunny

Steve,

I was quite intrigued by your description of using "...moving z-score plus standard deviation (two variables)...." for changing volatility. I was wondering if it would be possible for you to post an example of how you accomplish this. I attempted several ways of combining them; however, I have to admit that I failed miserably in my trials.

I would include to your wish list (from Steve) the ability to see information pertinent to each prediction on a chart shown as a table. Sometimes it is handy to have a list of different types of information for each prediction.

For instance, I work with several predictions on a chart at once, and sometimes I make mistakes with regards to the setup of some of these predictions. A list showing the number of neurons used for predicting in each prediction, the objective function used (for instance, maximize winners minus losers), the minimum and maximum dates for training, what is being predicted, what inputs were included, etc.

It seems kind of irrelevant information, but when you make a mistake with several tens of predictions, it takes a while to find the prediction causing a problem. A list showing the information from different predictions would allow a quick glimpse to find if one of the predictions was not "lined up" with the others.

Best regards,

Sunny

It's difficult to provide exact reasons without seeing the model, however these are some
points:

1. You mention that the equity curve is good at the beginning and flat at the end. That suggests
that you're running the GA on a certain period of time, and your "out of sample" is recent (presumably the flat part). A GA will generally do a good job of curve fitting because that's what it's designed to do. So the "out of sample" (provided you haven't curve fitted by manually curve fitting, i.e. stock selection etc.) becomes the measurement of how well your model is working.
I.E. If you've validated with enough trades for the DOF and the out of sample is poor, then the model more than likely doesn't work, and the model needs refining or replacing.

The GA always tries to fit over the data you provide it, i.e. if you use the GA over 8 years, then
the results should be fairly consistant during that time (provided the market has the opportunity to make money). Which is why you need the out of sample to validate it.

2. Regarding DOF, you can't really cheat as such. However you can make better indicators that
have fewer DOF. It's feasible to build an indicator (assuming the 2 indicators you are using are the same in the short and long), such that you have 2 indicators for long and short with a 3rd variable which essentially determines essentially becomes the adaption between short and long, that would give you 3 DOF and save 1 DOF, as currently you have duplication of information, essentially you're removing correlated information by removing that 1 DOF.

If you can get DOF really low, i.e. 1 DOF (maybe 2), then you can get into piecewise linear approach of curve fitting (you still need to at least validate on an out of sample, until you're happy the model works).

3. Also watch out for lag. I get the impression (although you don't explicitly say), that you're
using lagging indicators.

If possible, post your model to the forum, and we can take a further look at it.

Hi Dan,

DOF means a lot of different things to different people, however the way I approach
it is as follows.

To me a degree of freedom is an item that can change in a model. This could be:
1. A parameter to an indicator
2. Choice of indicator
3. Choice of security

All this is pretty vague, so hopefully the following examples will clarify it:

Model Inputs: RSI(x) on 1 security where x is optimized.
Answer: 1 DOF as x is a variable parameter i.e. it can change.

Model Inputs: RSI(5) on 1 security.
Answer: 1 DOF (as you need to validate the model on something).

Model Inputs: MACD(close,12,26) on 1 security
Answer: 1 DOF (as you need to validate the model on something).

Model Inputs: MACD(close,x,y) on 1 security where x/y are optimized.
Answer: 2 DOF (x and y)

Model Inputs: MACD(RSI (z), x, y) on 1 security where z/x/y are optimized.
Answer: 3 DOF (x, y and z)

Model Inputs: MACD (RSI (z), x, y) where z/x/y are optimized, and then we try
different stocks against it to find which ones perform best.
Answer: 4 DOF (x,y,z and stock selection)

Model Inputs: Indicator(x) where x is optimized, and we try many different indicators
to find one that works on 1 security.
Answer: 2 DOF (x and Indicator selection)

Model Inputs: MACD(close,5,20) where we just guessed 5,20 as being the parameters
on 1 security
Answer: 1 DOF (as you need to validate the model on something)

Model Inputs: MACD(close,5,20) however, we tried many different values for 5 and 20 until we found the ones that worked on 1 security.
Answer: 2 DOF (becuase you were manually changing both the 5 and 20).

So if you let the optimizer choose a value, 1 DOF gets added. If you
manually choose a value through experimentation, 1 DOF gets added.

This thread is about curve fitting. I also refer you to Steve Ward's tips on preventing
over-optimization http://www.ward.net/cgi-bin/viewtip.asp?ID=105 as a guideline for
what you can do to avoid it.

So, lets start off with what a GA (Genetic Algorithm) is, to remove some of the mysticism behind the GA built into Neuroshell. Personally I believe that it's
by understanding the principles of this that it can be better used to advantage.
The GA is a very powerful tool if used correctly, if used incorrectly it can sink
you.

You've probably come across the following problem, you build your
system, keep optimizing various types of system until you find one that does well,
then you trade it in realtime, and poof, that well performing system eats you alive.
If you've done everything else correctly, i.e. tested on out samples and used walk forwards, then the chances are you've just incorrectly curve fitted without realizing it.

So what is curve fitting? If you imagine your trading system like this, you
have inputs and you have an output (trading signals). You have a black box in the middle which translates between. Essentially the output is a function
of the input. I.E. Output=f (Input1..Input N)

The output is the curve, i.e. it's a varying function, and the idea is that we have to
design the function so that it fits that curve.

So, lets translate this to the NST world. We use a bunch of indicators to go into
our "function", and then see how well the function works (performance). However
it doesn't do too well, so we use the optimization feature in NST (a GA) to alter
the parameters to the indicators to make the function fit the curve better.

A Genetic Algorithm (GA) is just a tool to reduce the search space. For instance
if you had 5 indicators with a total of 10 possible parameters, then to try every
possible combination would take a long time. Trying every possibility is a brute force
method and isn't practical unless your model is extremely simple.

A GA looks at the problem differently. If we wanted to find the highest peak in a range of mountains, then visiting every mountain takes too long, so a GA
uses a targetted approach. I.E. You guess a local peak to begin with. It probably
isn't the highest peak, so you guess again. Then using a chromosome/gene
model borrowed from biology, where you have survival of the fittest, you match the good parameters of the mountains and keep going. Essentially you keep going, at every generation, the fittest members survive to keep going, until you can make no
more "reasonable" improvement. I.E. Your solution evolves to find the best answer
just like life on earth. What's happening is your taking spot readings over the range
and homing in on the highest mountain.

A GA has a fitness function (in this case the height of the mountain), in the case of
trading, it's your goal. The GA is a tool to help us fit the curve. A brute force method can be better than a GA, but if a GA doesn't reach the correct answer, it will likely
reach one that's close. I.E. In the trade off between brute force and a GA, GA is
really only the practical way to go, although brute force may be occasionally a little
more superior in result.

So lets try some examples of incorrectly curve fitting with a few examples.

CURVE FITTING WITH TOO LITTLE DATA:

So we toss some coins. Coins can be heads or tails and our goal is to build a perfect
coin toss predictor. We toss 3 times, and get heads each time. Therefore we
optimize our solution, and build a perfect coin tosser that always generates heads
as the answer. So what's wrong?

Well, our curve is heads/tails, but we took such a small sample (of size 3), that
we didn't see the real picture. I.E. We tried to fit a curve where we couldn't see the whole curve. In trading, this is a classic mistake that is commonly made. We genetically optimize with not enough data. Remember from before that to be
reasonably confident that we haven't incorrectly curve fitted the data, we need
30 trades per degree of freedom (DOF) for every variable in the model.

This shows up as, building a model that optimizes well, then trades poorly in real time.
If you tested with adequate data, you'd have found out that it really was poor in the
first place.

CURVE FITTING BY SELECTION: STOCK PICKING

We can also incorrectly curve fit by picking results, without even using a GA.

For instance, if you were to trade say 10 stocks randomly for a period of time,
you'd likely make money on some and lose money on others. Just like tossing
a coin would produce heads and tails.

So you have your perfect model and you want to trade, but it works on some stocks
not others, so you plug in 100 stocks to find out which ones do well and which ones
do poorly, and keep the good ones. Well you've just incorrectly curve fitted by
another means. (or another way of looking at it is rendered your out of sample to be in sample). This is because out of any population (the 100), if you pick and choose your sample (the good ones), then your sample is no longer truely representative
of your population.

CURVE FITTING BY SELECTION: INDICATORS

So, instead of picking the best stocks to use in your model, you pick the best indicators, i.e. just keep plugging at it until you find indicators that work.
Again, just another form of incorrect curve fitting for the same reason as the
last.

CURVE FITTING BY SELECTION: PICKING THE BEST RESULTS

So you keep trying models until you find the best one. Again, just incorrectly curve fitting.

As you can see, this is a huge problem, there are so many ways to incorrectly
curve fit. Anywhere where you pick and choose, or try different things open you
up to curve fitting.

One solution might be to create another out of sample testing to get around the problem. But again, if you pick and choose between those out of samples, you're
opening yourself up to the same problem again.

So, incorrectly curve fitting is not 100% avoidable, but needs to be realized and
managed. Personally I follow this method to avoid it as much as possible:

1. Never try things out in a model in an untargetted approach, and
this is where these threads about design models come into the picture. Start off
with a goal, and design a model to fit that goal, don't just guess at methods or
indicators that will work, start off with solid design from the ground up.

2. Use a GA to improve good models, not to make bad models work.

3. If using a GA, use it at the end of the process, i.e. as a final improvement to an
already good model.

4. Use sufficient data to test with.

5. Always keep additional out of samples to test on. A good out of sample is
always paper trading.

6. Never pick and choose results, stocks or anything else. (At least not without
being aware of it and knowing the effect).

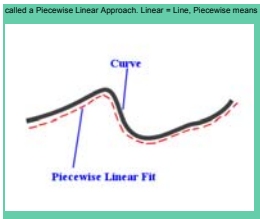
7. Keep degrees of freedom low. I.E. The smaller the DOF, the less data you
need to validate which makes everything a lot simpler to test.

USING CURVE FITTING TO ADVANTAGE:

There is another way to approach curve fitting and make it work to your advantage. At first it seems like a crazy approach, but there are good reasons why it works. That is to keep DOF small and optimize frequently.

The reason for this is because of the curve fitting. Normally we wish to fit that curve perfectly, however, any curve can be approximated by a series of small lines. This is

called a Piecewise Linear Approach. Linear = Line, Piecewise means small pieces.



I.E. If you keep Degrees Of Freedom (DOF) low so that your fit can be validated in minimal time, i.e. you're creating a small line, then it can fit (approximately) the curve of your function for a small period of time. You then reoptimize frequently to get additional small segments of lines.

Re: Curve fitting. What it is, how to avoid it and how to use it to advantage

Date :11/25/2005 4:49:15 PM Poster : Steve ward

The Prediction Wizard always uses z-score, as do the add-ons AT2 and NI. ANI, however, has no normalization across inputs, so only there is it really necessary to normalize across inputs. Normalization over time (detrending) is really where you need to be careful. Use indicators that are already normalized (like RSI, etc) or if using raw prices, then use change, percent change, spread from a moving average or index, etc.

On 11/22/2005 12:39:52 PM Steve Eberbach wrote:
Hi Mark: It is for this reason (changing volatility) that I have always converted all my indicators into moving z-score plus standard deviation (two variables). That way I have the inputs I need to test if there is useful information in the changes of volatility of each input. Another benefit of z-score is that the numeric indicators are nicely normalized, making it easier for me to read all my charts, since then I can put several indicators of different colors on one chart without severe vertical axis scaling problems which arise when trying to draw comparative charts.

Since Steve has written normalization into the neural nets, maybe he could include an option to simply display the input indicators as normalized for the prediction wizard, wherever these are in the memory, whether it is plus-minus a range, or z-score, or something else.

On 11/20/2005 3:00:07 PM Mark Simpson wrote:
Hi Dan,

First of all, you're not using an out of sample test as such, because the optimization date range is the same as the paper trading date range. Though this isn't causing the flat spot, it doesn't provide validation of the model either. I.E. you're validating the performance of the model with exactly the same data you're curve fitting the model to work best with. In NST you can seperate out the paper trading date range from the optimization range. However when you do that, you'll see the model doesn't perform too well anymore.

Regarding the flat spot. As Steve said, the market dynamics have changed. If you put a volatility indicator on that same chart, you'll see that around the beginning of 2003, volatility significantly dropped. The model worked well in a high volatility situation but not in a low volatility situation. Unfortunately, the DOF issue precludes you from producing a new model yet, i.e. you don't have enough recent data.

Assuming the model did successfully validate in paper trading at some point in time, then the only other way around the change in market this would be to normalize time, i.e. change the underlying data, this would produce volatility which was consistant and indicators which were "better behaved".

>Dan Melton

It's difficult to provide exact reasons without seeing the model, however these are some points:

1. You mention that the equity curve is good at the beginning and flat at the end. That suggests that you're running the GA on a certain period of time, and your "out of sample" is recent (presumably the flat part). A GA will generally do a good job of curve fitting because that's what it's designed to do. So the "out of sample" (provided you haven't curve fitted by manually curve fitting, i.e. stock selection etc.) becomes the measurement of how well your model is working.
I.E. If you've validated with enough trades for the DOF and the out of sample is poor, then the model more than likely doesn't work, and the model needs refining or replacing.

The GA always tries to fit over the data you provide it, i.e. if you use the GA over 8 years, then the results should be fairly consistant during that time (provided the market has the opportunity to make money). Which is why you need the out of sample to validate it.

2. Regarding DOF, you can't really cheat as such. However you can make better indicators that have fewer DOF. It's feasible to build an indicator (assuming the 2 indicators you are using are the same in the short and long), such that you have 2 indicators for long and short with a 3rd variable which essentially determines essentially becomes the adaption between short and long, that would give you 3 DOF and save 1 DOF, as currently you have duplication of information, essentially you're removing correlated information by removing that 1 DOF.

If you can get DOF really low, i.e. 1 DOF (maybe 2), then you can get into piecewise linear approach of curve fitting (you still need to at least validate on an out of sample, until you're happy the model works).

3. Also watch out for lag. I get the impression (although you don't explicitly say), that you're using lagging indicators.

If possible, post your model to the forum, and we can take a further look at it.

Hi Dan,

DOF means a lot of different things to different people, however the way I approach
it is as follows.

To me a degree of freedom is an item that can change in a model. This could be:
1. A parameter to an indicator
2. Choice of indicator
3. Choice of security

All this is pretty vague, so hopefully the following examples will clarify it:

Model Inputs: RSI(x) on 1 security where x is optimized.
Answer: 1 DOF as x is a variable parameter i.e. it can change.

Model Inputs: RSI(5) on 1 security.
Answer: 1 DOF (as you need to validate the model on something).

Model Inputs: MACD(close,12,26) on 1 security
Answer: 1 DOF (as you need to validate the model on something).

Model Inputs: MACD(close,x,y) on 1 security where x/y are optimized.
Answer: 2 DOF (x and y)

Model Inputs: MACD(RSI (z), x, y) on 1 security where z/x/y are optimized.
Answer: 3 DOF (x, y and z)

Model Inputs: MACD (RSI (z), x, y) where z/x/y are optimized, and then we try
different stocks against it to find which ones perform best.
Answer: 4 DOF (x,y,z and stock selection)

Model Inputs: Indicator(x) where x is optimized, and we try many different indicators
to find one that works on 1 security.
Answer: 2 DOF (x and Indicator selection)

Model Inputs: MACD(close,5,20) where we just guessed 5,20 as being the parameters
on 1 security.
Answer: 1 DOF (as you need to validate the model on something)

Model Inputs: MACD(close,5,20) however, we tried many different values for 5 and 20 until we found the ones that worked on 1 security.
Answer: 2 DOF (becuase you were manually changing both the 5 and 20).

So if you let the optimizer choose a value, 1 DOF gets added. If you
manually choose a value through experimentation, 1 DOF gets added.

just like life on earth. What's happening is your taking spot readings over the range
and homing in on the highest mountain.

A GA has a fitness function (in this case the height of the mountain), in the case of
trading, it's your goal. The GA is a tool to help us fit the curve. A brute force method can be better than a GA, but if a GA doesn't reach the correct answer, it will likely
reach one that's close. I.E. In the trade off between brute force and a GA, GA is
really only the practical way to go, although brute force may be occasionally a little
more superior in result.

So lets try some examples of incorrectly curve fitting with a few examples.

CURVE FITTING WITH TOO LITTLE DATA:

So we toss some coins. Coins can be heads or tails and our goal is to build a perfect
coin toss predictor. We toss 3 times, and get heads each time. Therefore we
optimize our solution, and build a perfect coin tosser that always generates heads
as the answer. So what's wrong?

Well, our curve is heads/tails, but we took such a small sample (of size 3), that
we didn't see the real picture. I.E. We tried to fit a curve where we couldn't see the whole curve. In trading, this is a classic mistake that is commonly made. We genetically optimize with not enough data. Remember from before that to be
reasonably confident that we haven't incorrectly curve fitted the data, we need
30 trades per degree of freedom (DOF) for every variable in the model.

This shows up as, building a model that optimizes well, then trades poorly in real time.
If you tested with adequate data, you'd have found out that it really was poor in the
first place.

CURVE FITTING BY SELECTION: STOCK PICKING

We can also incorrectly curve fit by picking results, without even using a GA.

For instance, if you were to trade say 10 stocks randomly for a period of time,
you'd likely make money on some and lose money on others. Just like tossing
a coin would produce heads and tails.

So you have your perfect model and you want to trade, but it works on some stocks
not others, so you plug in 100 stocks to find out which ones do well and which ones
do poorly, and keep the good ones. Well you've just incorrectly curve fitted by
another means. (or another way of looking at it is rendered your out of sample to be in sample). This is because out of any population (the 100), if you pick and choose your sample (the good ones), then your sample is no longer truely representative
of your population.

CURVE FITTING BY SELECTION: INDICATORS

So, instead of picking the best stocks to use in your model, you pick the best indicators, i.e. just keep plugging at it until you find indicators that work.
Again, just another form of incorrect curve fitting for the same reason as the
last.

CURVE FITTING BY SELECTION: PICKING THE BEST RESULTS

So you keep trying models until you find the best one. Again, just incorrectly curve fitting.

As you can see, this is a huge problem, there are so many ways to incorrectly
curve fit. Anywhere where you pick and choose, or try different things open you
up to curve fitting.

One solution might be to create another out of sample testing to get around the problem. But again, if you pick and choose between those out of samples, you're
opening yourself up to the same problem again.

So, incorrectly curve fitting is not 100% avoidable, but needs to be realized and
managed. Personally I follow this method to avoid it as much as possible:

1. Never try things out in a model in an untargetted approach, and
this is where these threads about design models come into the picture. Start off
with a goal, and design a model to fit that goal, don't just guess at methods or
indicators that will work, start off with solid design from the ground up.

2. Use a GA to improve good models, not to make bad models work.

3. If using a GA, use it at the end of the process, i.e. as a final improvement to an
already good model.

4. Use sufficient data to test with.

5. Always keep additional out of samples to test on. A good out of sample is
always paper trading.

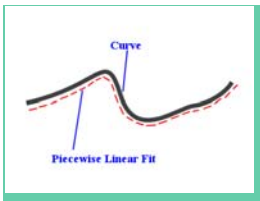
6. Never pick and choose results, stocks or anything else. (At least not without
being aware of it and knowing the effect).

7. Keep degrees of freedom low. I.E. The smaller the DOF, the less data you
need to validate which makes everything a lot simpler to test.

USING CURVE FITTING TO ADVANTAGE:

There is another way to approach curve fitting and make it work to your advantage. At first it seems like a crazy approach, but there are good reasons why it works. That is to keep DOF small and optimize frequently.

The reason for this is because of the curve fitting. Normally we wish to fit that curve perfectly, however, any curve can be approximated by a series of small lines. This is
called a Piecewise Linear Approach. Linear = Line, Piecewise means small pieces.



I.E. If you keep Degrees Of Freedom (DOF) low so that your fit can be validated in minimal time, i.e. you're creating a small line, then it can fit (approximately) the curve of your function for a small period of time. You then reoptimize frequently to get additional small segments of lines.

Re: Curve fitting. What it is, how to avoid it and how to use it to advantage

Date :11/26/2005 6:41:50 PM Poster : Steve Eberbach

Sunny:

What I use is a spreadsheet called WaveWi$e to convert my files to log-normalized format, and Z-scores for the log normalized version of the data. This I do because I use very long data sets for stocks which range over 50 years' time to find the cycles which have persisted the longest time first, or even more relevantly, the cycles and correlations which have "always" made a comeback even if they almost disappear for a while. When run through the nets, if the neural net's lookback window is different from the one I chose, there will be a doubly applied z-score normalization.

I append an abbreviation, such as "Z40" to, for example, DJICLOSE, to indicate the input dow jones industrials close, z-score of a 40 bar moving window. I also keep the standard deviation associated with that 40 bar window, which is otherwise discarded information when just normalizing by z-score. That standard deviation represents the average variance from the 40 bar moving average, the average amplitude of variance from that moving average. The z-score represents "how many" of these standard average variances (differences squared) the present bar's value is from the moving average at the present bar. If both the z-score and the associated 40 bar standard deviation are available to the neural net as choices for input, then the neural net can "decide" if the local (40 bar) variance has any modulating effect on the significance of the normalized input, the z-score.

So, in the case of Steve Ward's add-ons or the prediction wizard, you would add another input, "DJICLOSESD40" if your window length, the "look back length" was 40 bars, along with the existing input, "DJICLOSE" which was normalized with the lookback window size, 40 bars, to give your network information of local volatility from which that normalization was automatically derived by the network's normalizer. So besides normalization "across inputs" as Steve points out, you also have normalization "across time intervals".

Steve

On 11/25/2005 4:49:15 PM Steve ward wrote:

It's difficult to provide exact reasons without seeing the model, however these are some points:

1. You mention that the equity curve is good at the beginning and flat at the end. That suggests that you're running the GA on a certain period of time, and your "out of sample" is recent (presumably the flat part). A GA will generally do a good job of curve fitting because that's what it's designed to do. So the "out of sample" (provided you haven't curve fitted by manually curve fitting, i.e. stock selection etc.) becomes the measurement of how well your model is working.
I.E. If you've validated with enough trades for the DOF and the out of sample is poor, then the model more than likely doesn't work, and the model needs refining or replacing.

The GA always tries to fit over the data you provide it, i.e. if you use the GA over 8 years, then the results should be fairly consistant during that time (provided the market has the opportunity to make money). Which is why you need the out of sample to validate it.

2. Regarding DOF, you can't really cheat as such. However you can make better indicators that
have fewer DOF. It's feasible to build an indicator (assuming the 2 indicators you are using are the same in the short and long), such that you have 2 indicators for long and short with a 3rd variable which essentially determines
essentially becomes the adaption between short and long, that would give you 3 DOF and save 1 DOF, as currently you have duplication of information, essentially you're removing correlated information by removing that 1 DOF.

If you can get DOF really low, i.e. 1 DOF (maybe 2), then you can get into piecewise linear approach of curve fitting (you still need to at least validate on an out of sample, until you're happy the model works).

3. Also watch out for lag. I get the impression (although you don't explicitly say), that you're
using lagging indicators.

If possible, post your model to the forum, and we can take a further look at it.

Hi Dan,

DOF means a lot of different things to different people, however the way I approach
it is as follows.

To me a degree of freedom is an item that can change in a model. This could be:
1. A parameter to an indicator
2. Choice of indicator
3. Choice of security

All this is pretty vague, so hopefully the following examples will clarify it:

Model Inputs: RSI(x) on 1 security where x is optimized.
Answer: 1 DOF as x is a variable parameter i.e. it can change.

Model Inputs: RSI(5) on 1 security.
Answer: 1 DOF (as you need to validate the model on something).

Model Inputs: MACD(close,12,26) on 1 security
Answer: 1 DOF (as you need to validate the model on something).

Model Inputs: MACD(close,x,y) on 1 security where x/y are optimized.
Answer: 2 DOF (x and y)

Model Inputs: MACD(RSI (z), x, y) on 1 security where z/x/y are optimized.
Answer: 3 DOF (x, y and z)

Model Inputs: MACD (RSI (z), x, y) where z/x/y are optimized, and then we try
different stocks against it to find which ones perform best.
Answer: 4 DOF (x,y,z and stock selection)

Model Inputs: Indicator(x) where x is optimized, and we try many different indicators
to find one that works on 1 security.
Answer: 2 DOF (x and Indicator selection)

Model Inputs: MACD(close,5,20) where we just guessed 5,20 as being the parameters
on 1 security.
Answer: 1 DOF (as you need to validate the model on something)

Model Inputs: MACD(close,5,20) however, we tried many different values for 5 and 20 until we found the ones that worked on 1 security.
Answer: 2 DOF (becuase you were manually changing both the 5 and 20).

So if you let the optimizer choose a value, 1 DOF gets added. If you
manually choose a value through experimentation, 1 DOF gets added.

On 8/30/2005 2:24:54 PM Mark Simpson wrote:
This thread is about curve fitting. I also refer you to Steve Ward's tips on preventing
over-optimization http://www.ward.net/cgi-bin/viewtip.asp?ID=105 as a guideline for
what you can do to avoid it.

So, lets start off with what a GA (Genetic Algorithm) is, to remove some of the mysticism behind the GA built into Neuroshell. Personally I believe that it's
by understanding the principles of this that it can be better used to advantage.
The GA is a very powerful tool if used correctly, if used incorrectly it can sink
you.

You've probably come across the following problem, you build your
system, keep optimizing various types of system until you find one that does well,
then you trade it in realtime, and poof, that well performing system eats you alive.
If you've done everything else correctly, i.e. tested on out samples and used walk forwards, then the chances are you've just incorrectly curve fitted without realizing it.

So what is curve fitting? If you imagine your trading system like this, you
have inputs and you have an output (trading signals). You have a black box in the middle which translates between. Essentially the output is a function
of the input. I.E. Output=f (input1..Input N)

The output is the curve, i.e. it's a varying function, and the idea is that we have to
design the function so that it fits that curve.

So, lets translate this to the NST world. We use a bunch of indicators to go into
our "function", and then see how well the function works (performance). However
it doesn't do too well, so we use the optimization feature in NST (a GA) to alter
the parameters to the indicators to make the function fit the curve better.

A Genetic Algorithm (GA) is just a tool to reduce the search space. For instance
if you had 5 indicators with a total of 10 possible parameters, then to try every
possible combination would take a long time. Trying every possibility is a brute force
method and isn't practical unless your model is extremely simple.

A GA looks at the problem differently. If we wanted to find the highest peak in a range of mountains, then visiting every mountain takes too long, so a GA
uses a targetted approach. I.E. You guess a local peak to begin with. It probably
isn't the highest peak, so you guess again. Then using a chromosome/gene
model borrowed from biology, where you have survival of the fittest, you match the good parameters of the mountains and keep going. Essentially you keep going, at every generation, the fittest members survive to keep going, until
you can make no more "reasonable" improvement. I.E. Your solution evolves to find the best answer
just like life on earth. What's happening is your taking spot readings over the range
and homing in on the highest mountain.

A GA has a fitness function (in this case the height of the mountain), in the case of
trading, it's your goal. The GA is a tool to help us fit the curve. A brute force method can be better than a GA, but if a GA doesn't reach the correct answer, it will likely
reach one that's close. I.E. In the trade off between brute force and a GA, GA is
really only the practical way to go, although brute force may be occasionally a little
more superior in result.

So lets try some examples of incorrectly curve fitting with a few examples.

CURVE FITTING WITH TOO LITTLE DATA:

So we toss some coins. Coins can be heads or tails and our goal is to build a perfect
coin toss predictor. We toss 3 times, and get heads each time. Therefore we
optimize our solution, and build a perfect coin tosser that always generates heads
as the answer. So what's wrong?

Well, our curve is heads/tails, but we took such a small sample (of size 3), that
we didn't see the real picture. I.E. We tried to fit a curve where we couldn't see the whole curve. In trading, this is a classic mistake that is commonly made. We genetically optimize with not enough data. Remember from before that to
be
reasonably confident that we haven't incorrectly curve fitted the data, we need
30 trades per degree of freedom (DOF) for every variable in the model.

This shows up as, building a model that optimizes well, then trades poorly in real time.
If you tested with adequate data, you'd have found out that it really was poor in the
first place.

CURVE FITTING BY SELECTION: STOCK PICKING

We can also incorrectly curve fit by picking results, without even using a GA.

For instance, if you were to trade say 10 stocks randomly for a period of time,
you'd likely make money on some and lose money on others. Just like tossing
a coin would produce heads and tails.

So you have your perfect model and you want to trade, but it works on some stocks
not others, so you plug in 100 stocks to find out which ones do well and which ones
do poorly, and keep the good ones. Well you've just incorrectly curve fitted by
another means. (or another way of looking at it is rendered your out of sample to be in sample). This is because out of any population (the 100), if you pick and choose your sample (the good ones), then your sample is no longer truely
representative of your population.

CURVE FITTING BY SELECTION: INDICATORS

So, instead of picking the best stocks to use in your model, you pick the best indicators, i.e. just keep plugging at it until you find indicators that work.
Again, just another form of incorrect curve fitting for the same reason as the
last.

CURVE FITTING BY SELECTION: PICKING THE BEST RESULTS

So you keep trying models until you find the best one. Again, just incorrectly curve fitting.

As you can see, this is a huge problem, there are so many ways to incorrectly
curve fit. Anywhere where you pick and choose, or try different things open you
up to curve fitting.

One solution might be to create another out of sample testing to get around the problem. But again, if you pick and choose between those out of samples, you're
opening yourself up to the same problem again.

So, incorrectly curve fitting is not 100% avoidable, but needs to be realized and
managed. Personally I follow this method to avoid it as much as possible:

1. Never try things out in a model in an untargetted approach, and
this is where these threads about design models come into the picture. Start off
with a goal, and design a model to fit that goal, don't just guess at methods or
indicators that will work, start off with solid design from the ground up.

2. Use a GA to improve good models, not to make bad models work.

3. If using a GA, use it at the end of the process, i.e. as a final improvement to an
already good model.

4. Use sufficient data to test with.

5. Always keep additional out of samples to test on. A good out of sample is
always paper trading.

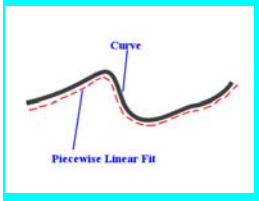
6. Never pick and choose results, stocks or anything else. (At least not without
being aware of it and knowing the effect).

7. Keep degrees of freedom low. I.E. The smaller the DOF, the less data you
need to validate which makes everything a lot simpler to test.

USING CURVE FITTING TO ADVANTAGE:

There is another way to approach curve fitting and make it work to your advantage. At first it seems like a crazy approach, but there are good reasons why it works. That is to keep DOF small and optimize frequently.

The reason for this is because of the curve fitting. Normally we wish to fit that curve perfectly, however, any curve can be approximated by a series of small lines. This is called a Piecewise Linear Approach. Linear = Line, Piecewise means small pieces.



I.E. If you keep Degrees Of Freedom (DOF) low so that your fit can be validated in minimal time, i.e. you're creating a small line, then it can fit (approximately) the curve of your function for a small period of time. You then reoptimize frequently to get additional small segments of lines.

Re: Curve fitting. What it is, how to avoid it and how to use it to advantage

Date :11/29/2005 7:36:29 AM Poster : Sunny

Steve,

Thank you for your thorough description.

I tried several different variation; however, there is something that I am doing wrong, and I would like to check with you on what I am doing:

Non-normalized

DJI-C

Lag(DJI-C, 40)

StndDev(ln(DJI-C) - lag(ln(DJI-C),1), 40)

StndDev(ln(DJI-C) - lag(ln(DJI-C),40), 40)

Normalized

ln(DJI-C) - lag(ln(DJI-C),1)

ln(DJI-C) - lag(ln(DJI-C),40)

StndNormalZScore(ln(DJI-C) - lag(ln(DJI-C),40),40)

StndNormalZScore(ln(DJI-C) - lag(ln(DJI-C),1), 40)

The normalized inputs are placed in a prediction.

I predicted the percentage change in the open.
The number of trading days into the prediction from the next open were 4.
I tried this both with optimization and without it.
I tried 4-walkforwards of 3-months.
I chose both long and short positions.
I used the trading rules greater than or less than zero.
The training objective was to maximize winners – losers.
The maximum training set size was 5 years.
The minimum training set size was 4 years.
Maximum number of hidden neurons during training were 80

The results that I got were not very good so I am sure that I did not follow your ideas correctly, but I am not sure where I am messing this up.

Regards,

Sunny

On 11/26/2005 6:41:50 PM Steve Eberbach wrote:
Sunny:

What I use is a spreadsheet called WaveWi$e to convert my files to log-normalized format, and Z-scores for the log normalized version of the data. This I do because I use very long data sets for stocks which range over 50 years' time to find the cycles which have persisted the longest time first, or even more relevantly, the cycles and correlations which have "always" made a comeback even if they almost disappear for a while. When run through the nets, if the neural net's lookback window is different from the one I chose, there will be a doubly applied z-score normalization.

I append an abbreviation, such as "Z40" to, for example, DJICLOSE, to indicate the input dow jones industrials close, z-score of a 40 bar moving window. I also keep the standard deviation associated with that 40 bar window, which is otherwise discarded information when just normalizing by z-score. That standard deviation represents the average variance from the 40 bar moving average, the average amplitude of variance from that moving average. The z-score represents "how many" of these standard average variances (differences squared) the present bar's value is from the moving average at the present bar. If both the z-score and the associated 40 bar standard deviation are available to the neural net as choices for input, then the neural net can "decide" if the local (40 bar) variance has any modulating effect on the significance of the normalized input, the z-score.

So, in the case of Steve Ward's add-ons or the prediction wizard, you would add another input, "DJICLOSESD40" if your window length, the "look back length" was 40 bars, along with the existing input, "DJICLOSE" which was normalized with the lookback window size, 40 bars, to give your network information of local volatility from which that normalization was automatically derived by the network's normalizer. So besides normalization "across inputs" as Steve points out, you also have normalization "across time intervals".

Steve

On 11/25/2005 4:49:15 PM Steve ward wrote:
The Prediction Wizard always uses z-score, as do the add-ons AT2 and NI. ANI, however, has no normalization across inputs, so only there is it really necessary to normalize across inputs. Normalization over time (detrending) is really where you need to be careful. Use indicators that are already normalized (like RSI, etc) or if using raw prices, then use change, percent change, spread from a moving average or index, etc.

On 11/22/2005 12:39:52 PM Steve Eberbach wrote:
Hi Mark: It is for this reason (changing volatility) that I have always converted all my indicators into moving z-score plus standard deviation (two variables). That way I have the inputs I need to test if there is useful information in the changes of volatility of each input. Another benefit of z-score is that the numeric indicators are nicely normalized, making it easier for me to read all my charts, since then I can put several indicators of different colors on one chart without severe vertical axis scaling problems which arise when trying to draw comparative charts.

Since Steve has written normalization into the neural nets, maybe he could include an option to simply display the input indicators as normalized for the prediction wizard, wherever these are in the memory, whether it is plus-minus a range, or z-score, or something else.

On 11/20/2005 3:00:07 PM Mark Simpson wrote:
Hi Dan,

First of all, you're not using an out of sample test as such, because the optimization date range is the same as the paper trading date range. Though this isn't causing the flat
spot, it doesn't provide validation of the model either. I.E. you're validating the performance of the model with exactly the same data you're curve fitting the model to work best with. In NST you can seperate out the paper trading date range from the optimization range. However when you do that, you'll see the model doesn't perform
too well anymore.

Regarding the flat spot. As Steve said, the market dynamics have changed. If
you put a volatility indicator on that same chart, you'll see that around the beginning of 2003, volatility significantly dropped. The model worked well in a high volatility situation but not in a low volatility situation.
Unfortunately, the DOF issue precludes you from
producing a new model yet, i.e. you don't have enough recent data.

Assuming the model did successfully validate in paper trading at some point in time,
then the only other way around the change in market this would be to normalize time,
i.e. change the underlying data, this would produce volatility which was consistant and indicators which were "better behaved".

Mark,

I'm attaching an example chart--a simple out-of-the-box crossover system from the Cybernetic Indicator add-on using Adaptive RVI. From here I sometimes elaborate with alternative exits and/or stops (results roughly similar). I'd also like to combine this with another system that kicks in when the market is trending as opposed to range-bound, but here is where I get into trouble in needing so many trades to account for the DOF for what is essentially two systems combined into one.

In case you don't have those indicators on your machine, I'm attaching a picture also (at least you can see the equity curve).

Thanks for any other thoughts you might have!

first place.

CURVE FITTING BY SELECTION: STOCK PICKING

We can also incorrectly curve fit by picking results, without even using a GA.

For instance, if you were to trade say 10 stocks randomly for a period of time,
you'd likely make money on some and lose money on others. Just like tossing
a coin would produce heads and tails.

So you have your perfect model and you want to trade, but it works on some stocks
not others, so you plug in 100 stocks to find out which ones do well and which ones
do poorly, and keep the good ones. Well you've just incorrectly curve fitted by
another means. (or another way of looking at it is rendered your out of sample to be in sample). This is because out of any population (the 100), if you pick and choose your sample (the good ones), then your sample is
no longer truely representative of your population.

CURVE FITTING BY SELECTION: INDICATORS

So, instead of picking the best stocks to use in your model, you pick the best indicators, i.e. just keep plugging at it until you find indicators that work.
Again, just another form of incorrect curve fitting for the same reason as the
last.

CURVE FITTING BY SELECTION: PICKING THE BEST RESULTS

So you keep trying models until you find the best one. Again, just incorrectly curve fitting.

As you can see, this is a huge problem, there are so many ways to incorrectly
curve fit. Anywhere where you pick and choose, or try different things open you
up to curve fitting.

One solution might be to create another out of sample testing to get around the problem: But again, if you pick and choose between those out of samples, you're
opening yourself up to the same problem again.

So, incorrectly curve fitting is not 100% avoidable, but needs to be realized and
managed. Personally I follow this method to avoid it as much as possible:

1. Never try things out in a model in an untargetted approach, and
this is where these threads about design models come into the picture. Start off
with a goal, and design a model to fit that goal, don't just guess at methods or
indicators that will work, start off with solid design from the ground up.

2. Use a GA to improve good models, not to make bad models work.

3. If using a GA, use it at the end of the process, i.e. as a final improvement to an
already good model.

4. Use sufficient data to test with.

5. Always keep additional out of samples to test on. A good out of sample is
always paper trading.

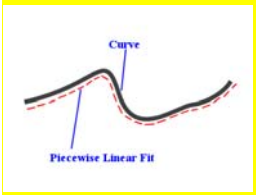
6. Never pick and choose results, stocks or anything else. (At least not without
being aware of it and knowing the effect).

7. Keep degrees of freedom low. I.E. The smaller the DOF, the less data you
need to validate which makes everything a lot simpler to test.

USING CURVE FITTING TO ADVANTAGE:

There is another way to approach curve fitting and make it work to your advantage. At first it seems like a crazy approach, but there are good reasons why it works. That is to keep DOF small and optimize frequently.

The reason for this is because of the curve fitting. Normally we wish to fit that curve perfectly, however, any curve can be approximated by a series of small lines. This is
called a Piecewise Linear Approach. Linear = Line, Piecewise means small pieces.



I.E. If you keep Degrees Of Freedom (DOF) low so that your fit can be validated in minimal time, i.e. you're creating a small line, then it can fit (approximately) the curve
of your function for a small period of time. You then reoptimize frequently to get additional small segments of lines.

Re: Curve fitting. What it is, how to avoid it and how to use it to advantage

Date :11/30/2005 7:36:07 PM Poster : Steve Eberbach

You specify:StndNormalZScore(ln(DJI-C) - lag(ln(DJI-C),1), 40)

This does make sense to normalize the "log delta" over a 40 bar window using z-score.

But you jumped to using a 40 bar lag, similarly normalized.

I would prefer using all the lags of:StndNormalZScore(ln(DJI-C) - lag(ln(DJI-C),1), 40)'

Which is the Zscore and log delta normalized close. You should derive all your lags from this normalized change, as well as other interesting indicators, such as the Cumulation of this normalized log-delta z-score normalized price called close. Not just lag 40. Lag 40 may not be relevant as other lags. 40 is just the window span I used for standard deviation of log delta over two months, which I found useful for s&p index and stocks.

Steve.

Thank you for your thorough description.

I tried several different variation; however, there is something that I am doing wrong, and I would like to check with you on what I am doing:

Non-normalized

DJI-C

Lag(DJI-C, 40)

StndDev(ln(DJI-C) - lag(ln(DJI-C),1), 40)

StndDev(ln(DJI-C) - lag(ln(DJI-C),40), 40)

Normalized

ln(DJI-C) - lag(ln(DJI-C),1)

ln(DJI-C) - lag(ln(DJI-C),40)

StndNormalZScore(ln(DJI-C) - lag(ln(DJI-C),40),40)

StndNormalZScore(ln(DJI-C) - lag(ln(DJI-C),1), 40)

The normalized inputs are placed in a prediction.

I predicted the percentage change in the open.
The number of trading days into the prediction from the next open were 4.
I tried this both with optimization and without it.
I tried 4-walkforwards of 3-months.

I chose both long and short positions.
I used the trading rules greater than or less than zero.
The training objective was to maximize winners – losers.
The maximum training set size was 5 years.
The minimum training set size was 4 years.
Maximum number of hidden neurons during training were 80

The results that I got were not very good so I am sure that I did not follow your ideas correctly, but I am not sure where I am messing this up.

Regards,

Sunny

Sunny:

What I use is a spreadsheet called WaveWi$e to convert my files to log-normalized format, and Z-scores for the log normalized version of the data. This I do because I use very long data sets for stocks which range over 50 years' time to find the cycles which have persisted the longest time first, or even more relevantly, the cycles and correlations which have "always" made a comeback even if they almost disappear for a while. When run through the nets, if the neural net's lookback window is different from the one I chose, there will be a doubly applied z-score normalization.

I append an abbreviation, such as "Z40" to, for example, DJICLOSE, to indicate the input dow jones industrials close, z-score of a 40 bar moving window. I also keep the standard deviation associated with that 40 bar window, which is otherwise discarded information when just normalizing by z-score. That standard deviation represents the average variance from the 40 bar moving average, the average amplitude of variance from that moving average. The z-score represents "how many" of these standard average variances (differences squared) the present bar's value is from the moving average at the present bar. If both the z-score and the associated 40 bar standard deviation are available to the neural net as choices for input, then the neural net can "decide" if the local (40 bar) variance has any modulating effect on the significance of the normalized input, the z-score.

So, in the case of Steve Ward's add-ons or the prediction wizard, you would add another input, "DJICLOSESD40" if your window length, the "look back length" was 40 bars, along with the existing input, "DJICLOSE" which was normalized with the lookback window size, 40 bars, to give your network information of local volatility from which that normalization was automatically derived by the network's normalizer. So besides normalization "across inputs" as Steve points out, you also have normalization "across time intervals".

Steve

On 11/20/2005 3:00:07 PM Mark Simpson wrote:
Hi Dan,

First of all, you're not using an out of sample test as such, because the optimization date range is the same as the paper trading date range. Though this isn't causing the flat
spot, it doesn't provide validation of the model either. I.E. you're validating the performance of the model with exactly the same data you're curve fitting the model to work best with. In NST you can seperate out the paper trading date range from the optimization range. However when you do that, you'll see the model doesn't perform
too well anymore.

Regarding the flat spot. As Steve said, the market dynamics have changed. If
you put a volatility indicator on that same chart, you'll see that around the beginning of 2003, volatility significantly dropped. The model worked well in a high volatility situation but not in a low volatility situation. Unfortunately, the DOF issue precludes you from
producing a new model yet, i.e. you don't have enough recent data.

Assuming the model did successfully validate in paper trading at some point in time,
then the only other way around the change in market this would be to normalize time,
i.e. change the underlying data, this would produce volatility which was consistant and indicators which were "better behaved".

It's difficult to provide exact reasons without seeing the model, however these are some
points:

1. You mention that the equity curve is good at the beginning and flat at the end. That suggests
that you're running the GA on a certain period of time, and your "out of sample" is recent (presumably the flat part). A GA will generally do a good job of curve fitting because that's what it's designed to do. So the "out of sample" (provided you haven't curve fitted by manually curve fitting, i.e. stock selection etc.) becomes the measurement of how well your model is working.
I.E. If you've validated with enough trades for the DOF and the out of sample is poor, then the model more than likely doesn't work, and the model needs refining or replacing.

The GA always tries to fit over the data you provide it, i.e. if you use the GA over 8 years, then
the results should be fairly consistant during that time (provided the market has the opportunity to make money). Which is why you need the out of sample to validate it.

2. Regarding DOF, you can't really cheat as such. However you can make better indicators that
have fewer DOF. It's feasible to build an indicator (assuming the 2 indicators you are using are the same in the short and long), such that you have 2 indicators for long and short with a 3rd variable which essentially determines essentially becomes the adaption between short and long, that would give you 3 DOF and save 1 DOF, as currently you have duplication of information, essentially you're removing correlated information by removing that 1 DOF.

If you can get DOF really low, i.e. 1 DOF (maybe 2), then you can get into piecewise linear approach of curve fitting (you still need to at least validate on an out of sample, until you're happy the model works).

3. Also watch out for lag. I get the impression (although you don't explicitly say), that you're
using lagging indicators.

If possible, post your model to the forum, and we can take a further look at it.

Hi Dan,

DOF means a lot of different things to different people, however the way I approach
it is as follows.

To me a degree of freedom is an item that can change in a model. This could be:
1. A parameter to an indicator
2. Choice of indicator
3. Choice of security

All this is pretty vague, so hopefully the following examples will clarify it:

Model Inputs: RSI(x) on 1 security where x is optimized.
Answer: 1 DOF as x is a variable parameter i.e. it can change.

Model Inputs: RSI(5) on 1 security.
Answer: 1 DOF (as you need to validate the model on something).

Model Inputs: MACD(close,12,26) on 1 security
Answer: 1 DOF (as you need to validate the model on something).

Model Inputs: MACD(close,x,y) on 1 security where x/y are optimized.
Answer: 2 DOF (x and y)

Model Inputs: MACD(RSI (z), x, y) on 1 security where z/x/y are optimized.
Answer: 3 DOF (x, y and z)

Model Inputs: MACD (RSI (z), x, y) where z/x/y are optimized, and then we try
different stocks against it to find which ones perform best.
Answer: 4 DOF (x,y,z and stock selection)

Model Inputs: Indicator(x) where x is optimized, and we try many different indicators
to find one that works on 1 security.
Answer: 2 DOF (x and Indicator selection)

Model Inputs: MACD(close,5,20) where we just guessed 5,20 as being the parameters
on 1 security.
Answer: 1 DOF (as you need to validate the model on something)

Model Inputs: MACD(close,5,20) however, we tried many different values for 5 and 20 until we found the ones that worked on 1 security.
Answer: 2 DOF (becuase you were manually changing both the 5 and 20).

So if you let the optimizer choose a value, 1 DOF gets added. If you
manually choose a value through experimentation, 1 DOF gets added.

On 8/30/2005 2:24:54 PM Mark Simpson wrote:
This thread is about curve fitting. I also refer you to Steve Ward's tips on preventing
over-optimization http://www.ward.net/cgi-bin/viewtip.asp?ID=105 as a guideline for
what you can do to avoid it.

So, lets start off with what a GA (Genetic Algorithm) is, to remove some of the mysticism behind the GA built into Neuroshell. Personally I believe that it's
by understanding the principles of this that it can be better used to advantage.
The GA is a very powerful tool if used correctly, if used incorrectly it can sink
you.

You've probably come across the following problem, you build your
system, keep optimizing various types of system until you find one that does well,
then you trade it in realtime, and poof, that well performing system eats you alive.
If you've done everything else correctly, i.e. tested on out samples and used walk forwards, then the chances are you've just incorrectly curve fitted without realizing it.

So what is curve fitting? If you imagine your trading system like this, you
have inputs and you have an output (trading signals). You have a black box in the middle which translates between. Essentially the output is a function
of the input. I.E. Output=f (Input1..Input N)

The output is the curve, i.e. it's a varying function, and the idea is that we have to
design the function so that it fits that curve.

So, lets translate this to the NST world. We use a bunch of indicators to go into
our "function", and then see how well the function works (performance). However
it doesn't do too well, so we use the optimization feature in NST (a GA) to alter
the parameters to the indicators to make the function fit the curve better.

A Genetic Algorithm (GA) is just a tool to reduce the search space. For instance
if you had 5 indicators with a total of 10 possible parameters, then to try every
possible combination would take a long time. Trying every possibility is a brute force
method and isn't practical unless your model is extremely simple.

A GA looks at the problem differently. If we wanted to find the highest peak in a range of mountains, then visiting every mountain takes too long, so a GA
uses a targetted approach. I.E. You guess a local peak to begin with. It probably
isn't the highest peak, so you guess again. Then using a chromosome/gene
model borrowed from biology, where you have survival of the fittest, you match the good parameters of the mountains and keep going. Essentially you keep going, at every generation, the fittest members
survive to keep going, until you can make no more "reasonable" improvement. I.E. Your solution evolves to find the best answer
just like life on earth. What's happening is your taking spot readings over the range
and homing in on the highest mountain.

A GA has a fitness function (in this case the height of the mountain), in the case of
trading, it's your goal. The GA is a tool to help us fit the curve. A brute force method can be better than a GA, but if a GA doesn't reach the correct answer, it will likely
reach one that's close. I.E. In the trade off between brute force and a GA, GA is
really only the practical way to go, although brute force may be occasionally a little
more superior in result.

So lets try some examples of incorrectly curve fitting with a few examples.

CURVE FITTING WITH TOO LITTLE DATA:

So we toss some coins. Coins can be heads or tails and our goal is to build a perfect
coin toss predictor. We toss 3 times, and get heads each time. Therefore we
optimize our solution, and build a perfect coin tosser that always generates heads
as the answer. So what's wrong?

Well, our curve is heads/tails, but we took such a small sample (of size 3), that
we didn't see the real picture. I.E. We tried to fit a curve where we couldn't see the whole curve. In trading, this is a classic mistake that is commonly made. We genetically optimize with not enough data.
Remember from before that to be
reasonably confident that we haven't incorrectly curve fitted the data, we need
30 trades per degree of freedom (DOF) for every variable in the model.

This shows up as, building a model that optimizes well, then trades poorly in real time.
If you tested with adequate data, you'd have found out that it really was poor in the
first place.

CURVE FITTING BY SELECTION: STOCK PICKING

We can also incorrectly curve fit by picking results, without even using a GA.

For instance, if you were to trade say 10 stocks randomly for a period of time,
you'd likely make money on some and lose money on others. Just like tossing
a coin would produce heads and tails.

So you have your perfect model and you want to trade, but it works on some stocks
not others, so you plug in 100 stocks to find out which ones do well and which ones
do poorly, and keep the good ones. Well you've just incorrectly curve fitted by
another means. (or another way of looking at it is rendered your out of sample to be in sample). This is because out of any population (the 100), if you pick and choose your sample (the good ones), then
your sample is no longer truely representative of your population.

CURVE FITTING BY SELECTION: INDICATORS

So, instead of picking the best stocks to use in your model, you pick the best indicators, i.e. just keep plugging at it until you find indicators that work.
Again, just another form of incorrect curve fitting for the same reason as the
last.

CURVE FITTING BY SELECTION: PICKING THE BEST RESULTS

So you keep trying models until you find the best one. Again, just incorrectly curve fitting.

As you can see, this is a huge problem, there are so many ways to incorrectly
curve fit. Anywhere where you pick and choose, or try different things open you
up to curve fitting.

One solution might be to create another out of sample testing to get around the problem. But again, if you pick and choose between those out of samples, you're
opening yourself up to the same problem again.

So, incorrectly curve fitting is not 100% avoidable, but needs to be realized and
managed. Personally I follow this method to avoid it as much as possible:

1. Never try things out in a model in an untargetted approach, and
this is where these threads about design models come into the picture. Start off

Also, I prefer 100*(ln(DJI-C)-ln(lag(DJI-C),1)), since it translates changes into a "reversible" percent change indicator. By that I mean if you accumulate these changes you restore the correct shape of the logarithmic price, on a percentage return basis, even if you go back and forth between changes and integrated (cumulative) changes many times, which does not happen if you use the standard "percent change" definition.

The standard percent change definition is fatally flawed. It will ruin your predictions, with a bias which makes a rise of 100 percent change equal to a decline of 50 percent change!

Steve

Hi Dan,

First of all, you're not using an out of sample test as such, because the optimization date range is the same as the paper trading date range. Though this isn't causing the flat spot, it doesn't provide validation of the model either. I.E. you're validating the performance of the model with exactly the same data you're curve fitting the model to work best with. In NST you can seperate out the paper trading date range from the optimization range. However when you do that, you'll see the model doesn't perform too well anymore.

Regarding the flat spot. As Steve said, the market dynamics have changed. If you put a volatility indicator on that same chart, you'll see that around the beginning of 2003, volatility significantly dropped. The model worked well in a high volatility situation but not in a low volatility situation. Unfortunately, the DOF issue precludes you from producing a new model yet, i.e. you don't have enough recent data.

Assuming the model did successfully validate in paper trading at some point in time, then the only other way around the change in market this would be to normalize time, i.e. change the underlying data, this would produce volatility which was consistant and indicators which were "better behaved".

It's difficult to provide exact reasons without seeing the model, however these are some
points:

1. You mention that the equity curve is good at the beginning and flat at the end. That suggests
that you're running the GA on a certain period of time, and your "out of sample" is recent (presumably the flat part). A GA will generally do a good job of curve fitting because that's what it's designed to do.
So the "out of sample" (provided you haven't curve fitted by manually curve fitting, i.e. stock selection etc.) becomes the measurement of how well your model is working.
I.E. If you've validated with enough trades for the DOF and the out of sample is poor, then the model more than likely doesn't work, and the model needs refining or replacing.

The GA always tries to fit over the data you provide it, i.e. if you use the GA over 8 years, then
the results should be fairly consistant during that time (provided the market has the opportunity to make money). Which is why you need the out of sample to validate it.

2. Regarding DOF, you can't really cheat as such. However you can make better indicators that
have fewer DOF. It's feasible to build an indicator (assuming the 2 indicators you are using are the same in the short and long), such that you have 2 indicators for long and short with a 3rd variable which essentially determines essentially becomes the adaption between short and long, that would give you 3 DOF and save 1 DOF, as currently you have duplication of information, essentially you're removing correlated information by removing that 1 DOF.

If you can get DOF really low, i.e. 1 DOF (maybe 2), then you can get into piecewise linear approach of curve fitting (you still need to at least validate on an out of sample, until you're happy the model works).

3. Also watch out for lag. I get the impression (although you don't explicitly say), that you're
using lagging indicators.

If possible, post your model to the forum, and we can take a further look at it.

Hi Dan,

DOF means a lot of different things to different people, however the way I approach
it is as follows.

To me a degree of freedom is an item that can change in a model. This could be:
1. A parameter to an indicator
2. Choice of indicator
3. Choice of security

All this is pretty vague, so hopefully the following examples will clarify it:

Model Inputs: RSI(x) on 1 security where x is optimized.
Answer: 1 DOF as x is a variable parameter i.e. it can change.

Model Inputs: RSI(5) on 1 security.
Answer: 1 DOF (as you need to validate the model on something).

Model Inputs: MACD(close,12,26) on 1 security
Answer: 1 DOF (as you need to validate the model on something).

Model Inputs: MACD(close,x,y) on 1 security where x/y are optimized.
Answer: 2 DOF (x and y)

Model Inputs: MACD(RSI (z), x, y) on 1 security where z/x/y are optimized.
Answer: 3 DOF (x, y and z)

Model Inputs: MACD (RSI (z), x, y) where z/x/y are optimized, and then we try
different stocks against it to find which ones perform best.
Answer: 4 DOF (x,y,z and stock selection)

Model Inputs: Indicator(x) where x is optimized, and we try many different indicators
to find one that works on 1 security.
Answer: 2 DOF (x and Indicator selection)

Model Inputs: MACD(close,5,20) where we just guessed 5,20 as being the parameters
on 1 security.
Answer: 1 DOF (as you need to validate the model on something)

Model Inputs: MACD(close,5,20) however, we tried many different values for 5 and 20 until we found the ones that worked on 1 security.
Answer: 2 DOF (becuase you were manually changing both the 5 and 20).

So if you let the optimizer choose a value, 1 DOF gets added. If you
manually choose a value through experimentation, 1 DOF gets added.

On 8/30/2005 2:24:54 PM Mark Simpson wrote:
This thread is about curve fitting. I also refer you to Steve Ward's tips on preventing
over-optimization http://www.ward.net/cgi-bin/viewtip.asp?ID=105 as a guideline for
what you can do to avoid it.

So, lets start off with what a GA (Genetic Algorithm) is, to remove some of the mysticism behind the GA built into Neuroshell. Personally I believe that it's
by understanding the principles of this that it can be better used to advantage.
The GA is a very powerful tool if used correctly, if used incorrectly it can sink
you.

You've probably come across the following problem, you build your
system, keep optimizing various types of system until you find one that does well,
then you trade it in realtime, and poof, that well performing system eats you alive.
If you've done everything else correctly, i.e. tested on out samples and used walk forwards, then the chances are you've just incorrectly curve fitted without realizing it.

So what is curve fitting? If you imagine your trading system like this, you
have inputs and you have an output (trading signals). You have a black box in the middle which translates between. Essentially the output is a function
of the input. I.E. Output=f (Input1 , Input N)

The output is the curve, i.e. it's a varying function, and the idea is that we have to
design the function so that it fits that curve.

So, lets translate this to the NST world. We use a bunch of indicators to go into

our "function", and then see how well the function works (performance). However
it doesn't do too well, so we use the optimization feature in NST (a GA) to alter
the parameters to the indicators to make the function fit the curve better.

A Genetic Algorithm (GA) is just a tool to reduce the search space. For instance
if you had 5 indicators with a total of 10 possible parameters, then to try every
possible combination would take a long time. Trying every possibility is a brute force
method and isn't practical unless your model is extremely simple.

A GA looks at the problem differently. If we wanted to find the highest peak in a range of mountains, then visiting every mountain takes too long, so a GA
uses a targetted approach. I.E. You guess a local peak to begin with. It probably
isn't the highest peak, so you guess again. Then using a chromosome/gene
model borrowed from biology, where you have survival of the fittest, you match the good parameters of the mountains and keep going. Essentially you keep going, at every generation, the fittest members
survive to keep going, until you can make no more "reasonable" improvement. I.E. Your solution evolves to find the best answer
just like life on earth. What's happening is your taking spot readings over the range
and homing in on the highest mountain.

A GA has a fitness function (in this case the height of the mountain), in the case of
trading, it's your goal. The GA is a tool to help us fit the curve. A brute force method can be better than a GA, but if a GA doesn't reach the correct answer, it will likely
reach one that's close. I.E. In the trade off between brute force and a GA, GA is
really only the practical way to go, although brute force may be occasionally a little
more superior in result.

So lets try some examples of incorrectly curve fitting with a few examples.

CURVE FITTING WITH TOO LITTLE DATA:

So we toss some coins. Coins can be heads or tails and our goal is to build a perfect
coin toss predictor. We toss 3 times, and get heads each time. Therefore we
optimize our solution, and build a perfect coin tosser that always generates heads
as the answer. So what's wrong?

Well, our curve is heads/tails, but we took such a small sample (of size 3), that
we didn't see the real picture. I.E. We tried to fit a curve where we couldn't see the whole curve. In trading, this is a classic mistake that is commonly made. We genetically optimize with not enough data.
Remember from before that to be
reasonably confident that we haven't incorrectly curve fitted the data, we need
30 trades per degree of freedom (DOF) for every variable in the model.

This shows up as, building a model that optimizes well, then trades poorly in real time.
If you tested with adequate data, you'd have found out that it really was poor in the
first place.

CURVE FITTING BY SELECTION: STOCK PICKING

We can also incorrectly curve fit by picking results, without even using a GA.

For instance, if you were to trade say 10 stocks randomly for a period of time,
you'd likely make money on some and lose money on others. Just like tossing
a coin would produce heads and tails.

So you have your perfect model and you want to trade, but it works on some stocks
not others, so you plug in 100 stocks to find out which ones do well and which ones
do poorly, and keep the good ones. Well you've just incorrectly curve fitted by
another means. (or another way of looking at it is rendered your out of sample to be in sample). This is because out of any population (the 100), if you pick and choose your sample (the good ones), then
your sample is no longer truely representative of your population.

CURVE FITTING BY SELECTION: INDICATORS

So, instead of picking the best stocks to use in your model, you pick the best indicators, i.e. just keep plugging at it until you find indicators that work.
Again, just another form of incorrect curve fitting for the same reason as the
last.

CURVE FITTING BY SELECTION: PICKING THE BEST RESULTS

So you keep trying models until you find the best one. Again, just incorrectly curve fitting.

As you can see, this is a huge problem, there are so many ways to incorrectly
curve fit. Anywhere where you pick and choose, or try different things open you
up to curve fitting.

One solution might be to create another out of sample testing to get around the problem. But again, if you pick and choose between those out of samples, you're
opening yourself up to the same problem again.

So, incorrectly curve fitting is not 100% avoidable, but needs to be realized and
managed. Personally I follow this method to avoid it as much as possible:

1. Never try things out in a model in an untargetted approach, and
this is where these threads about design models come into the picture. Start off
with a goal, and design a model to fit that goal, don't just guess at methods or
indicators that will work, start off with solid design from the ground up.

2. Use a GA to improve good models, not to make bad models work.

3. If using a GA, use it at the end of the process, i.e. as a final improvement to an
already good model.

4. Use sufficient data to test with.

5. Always keep additional out of samples to test on. A good out of sample is
always paper trading.

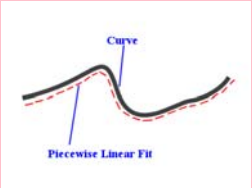
6. Never pick and choose results, stocks or anything else. (At least not without
being aware of it and knowing the effect).

7. Keep degrees of freedom low. I.E. The smaller the DOF, the less data you
need to validate which makes everything a lot simpler to test.

USING CURVE FITTING TO ADVANTAGE:

There is another way to approach curve fitting and make it work to your advantage. At first it seems like a crazy approach, but there are good reasons why it works. That is to keep DOF small and optimize
frequently.

The reason for this is because of the curve fitting. Normally we wish to fit that curve perfectly, however, any curve can be approximated by a series of small lines. This is
called a Piecewise Linear Approach. Linear = Line, Piecewise means small pieces.



I.E. If you keep Degrees Of Freedom (DOF) low so that your fit can be validated in minimal time, i.e. you're creating a small line, then it can fit (approximately) the curve
of your function for a small period of time. You then reoptimize frequently to get additional small segments of lines.

Postcript-Re: Curve fitting. What it is, how to avoid it and how to use it to advantage

Date :12/4/2005 4:03:20 AM Poster : Sunny

Steve,

First of all, I would like to thank you for taking the time to go over this procedure with me. I am attempting to answer here your last two posts on this topic.

I tried several different combinations, and I have done two different predictions in which I am using the StndNormalZScore and lag(sub(ln(close), ln(lag(close))).

I am still unsure if I am using these indicators correctly (according to your instructions). For this reason, I have posted a chart that includes both of these predictions. I have also included data in the chart.

The chart referenced in this post can be downloaded from the following link:

Steve Eberbach (data saved).cht

Moreover, I tried these prediction both with optimization and without it. I am including the results with optimization.

In addition, one of these predictions predicts the percent change in the open while the other prediction predicts mul2(100,sub(ln(close),ln(lag(close,1))))). Interestingly, if I change this last objective for the first one (percent change in the open), the results are more similar but still not the same.

I am wondering if you meant to use this last indicator as a prediction objective or as an input for a prediction.

I tried initially a larger set of lags as you suggested (and as I understood); however, not all of these lags were relevant. In order to save time (and file space), I discarded the other lags, and I left only two within each prediction.

Would you normally include in your predictions a larger set of lags? It appears that the amount of time to predict increases rapidly with several inputs of the same. For this reason, I am wondering if the correct procedure would be to predict without optimization and to allow the prediction wizard to choose the relevant inputs.

If you don't mind taking a look, I would value your comments regarding the procedure.

Regards,

Sunny

On 11/30/2005 7:59:03 PM Steve Eberbach wrote:
Also, I prefer 100*(ln(DJI-C)-ln(lag(DJI-C),1)), since it translates changes into a "reversible" percent change indicator. By that I mean if you accumulate these changes you restore the correct shape of the logarithmic price, on a percentage return basis, even if you go back and forth between changes and integrated (cumulative) changes many times, which does not happen if you use the standard "percent change" definition.

The standard percent change definition is fatally flawed. It will ruin your predictions, with a bias which makes a rise of 100 percent change equal to a decline of 50 percent change!

Steve

On 11/29/2005 7:36:29 AM Sunny wrote:
Steve,

Thank you for your thorough description.

I tried several different variation; however, there is something that I am doing wrong, and I would like to check with you on what I am doing:

Non-normalized

DJI-C

Lag(DJI-C, 40)

StndDev(ln(DJI-C) - lag(ln(DJI-C),1), 40)

StndDev(ln(DJI-C) - lag(ln(DJI-C),40), 40)

Normalized

ln(DJI-C) - lag(ln(DJI-C),1)

ln(DJI-C) - lag(ln(DJI-C),40)

StndNormalZScore(ln(DJI-C) - lag(ln(DJI-C),40),40)

StndNormalZScore(ln(DJI-C) - lag(ln(DJI-C),1), 40)

The normalized inputs are placed in a prediction.

I predicted the percentage change in the open.
The number of trading days into the prediction from the next open were 4.
I tried this both with optimization and without it.
I tried 4-walkforwards of 3-months.
I chose both long and short positions.
I used the trading rules greater than or less than zero.
The training objective was to maximize winners – losers.
The maximum training set size was 5 years.
The minimum training set size was 4 years.
Maximum number of hidden neurons during training were 80

The results that I got were not very good so I am sure that I did not follow your ideas correctly, but I am not sure where I am messing this up.

Regards,

Sunny

On 11/26/2005 6:41:50 PM Steve Eberbach wrote:
Sunny:

What I use is a spreadsheet called WaveWiSe to convert my files to log-normalized format, and Z-scores for the log normalized version of the data. This I do because I use very long data sets for stocks which range over 50 years' time to find the cycles which have persisted the longest time first, or even more relevantly, the cycles and correlations which have "always" made a comeback even if they almost disappear for a while. When run through the nets, if the neural net's lookback window is different from the one I chose, there will be a doubly applied z-score normalization.

I append an abbreviation, such as "Z40" to, for example, DJICLOSE, to indicate the input dow jones industrials close, z-score of a 40 bar moving window. I also keep the standard deviation associated with that 40 bar window, which is otherwise discarded information when just normalizing by z-score. That standard deviation represents the average variance from the 40 bar moving average, the average amplitude of variance from that moving average. The z-score represents "how many" of these standard average variances (differences squared) the present bar's value is from the moving average at the present bar. If both the z-score and the associated 40 bar standard deviation are available to the neural net as choices for input, then the neural net can "decide" if the local (40 bar) variance has any modulating effect on the significance of the normalized input, the z-score.

So, in the case of Steve Ward's add-ons or the prediction wizard, you would add another input, "DJICLOSESD40" if your window length, the "look back length" was 40 bars, along with the existing input, "DJICLOSE" which was normalized with the lookback window size, 40 bars, to give your network information of local volatility from which that normalization was automatically derived by the network's normalizer. So besides normalization "across inputs" as Steve points out, you also have normalization "across time intervals".

Steve

On 11/25/2005 4:49:15 PM Steve ward wrote:
The Prediction Wizard always uses z-score, as do the add-ons AT2 and NI. ANI, however, has no normalization across inputs, so only there is it really necessary to normalize across inputs. Normalization over time (detrending) is really where you need to be careful. Use indicators that are already normalized (like RSI, etc) or if using raw prices, then use change, percent change, spread from a moving average or index, etc.

On 11/22/2005 12:39:52 PM Steve Eberbach wrote:
Hi Mark: It is for this reason (changing volatility) that I have always converted all my indicators into moving z-score plus standard deviation (two variables). That way I have the inputs I need to test if there is useful information in the changes of volatility of each input. Another benefit of z-score is that the numeric indicators are nicely normalized, making it easier for me to read all my charts, since then I can put several indicators of different colors on one chart without severe vertical axis scaling problems which arise when trying to draw comparative charts.

Since Steve has written normalization into the neural nets, maybe he could include an option to simply display the input indicators as normalized for the prediction wizard, wherever these are in the memory, whether it is plus-minus a range, or z-score, or something else.

Model Inputs: MACD(RSI (z), x, y) on 1 security where z/x/y are optimized.
Answer: 3 DOF (x, y and z)

Model Inputs: MACD (RSI (z), x, y) where z/x/y are optimized, and then we try different stocks against it to find which ones perform best.
Answer: 4 DOF (x,y,z and stock selection)

Model Inputs: Indicator(x) where x is optimized, and we try many different indicators to find one that works on 1 security.
Answer: 2 DOF (x and Indicator selection)

Model Inputs: MACD(close,5,20) where we just guessed 5,20 as being the parameters on 1 security.
Answer: 1 DOF (as you need to validate the model on something)

Model Inputs: MACD(close,5,20) however, we tried many different values for 5 and 20 until we found the ones that worked on 1 security.
Answer: 2 DOF (becuase you were manually changing both the 5 and 20).

So if you let the optimizer choose a value, 1 DOF gets added. If you manually choose a value through experimentation, 1 DOF gets added.

This thread is about curve fitting. I also refer you to Steve Ward's tips on preventing over-optimization http://www.ward.net/cgi-bin/viewtip.asp?ID=105 as a guideline for what you can do to avoid it.

So, lets start off with what a GA (Genetic Algorithm) is, to remove some of the mysticism behind the GA built into Neuroshell. Personally I believe that it's by understanding the principles of this that it can be better used to advantage.
The GA is a very powerful tool if used correctly, if used incorrectly it can sink you.

You've probably come across the following problem, you build your system, keep optimizing various types of system until you find one that does well, then you trade it in realtime, and poof, that well performing system eats you alive.
If you've done everything else correctly, i.e. tested on out samples and used walk forwards, then the chances are you've just incorrectly curve fitted without realizing it.

So what is curve fitting? If you imagine your trading system like this, you have inputs and you have an output (trading signals). You have a black box in the middle which translates between. Essentially the output is a function of the input. I.E. Output=f (Input1..Input N)

The output is the curve, i.e. it's a varying function, and the idea is that we have to design the function so that it fits that curve.

So, lets translate this to the NST world. We use a bunch of indicators to go into our "function", and then see how well the function works (performance). However it doesn't do too well, so we use the optimization feature in NST (a GA) to alter the parameters to the indicators to make the function fit the curve better.

A Genetic Algorithm (GA) is just a tool to reduce the search space. For instance if you had 5 indicators with a total of 10 possible parameters, then to try every possible combination would take a long time. Trying every possibility is a brute force method and isn't practical unless your model is extremely simple.

A GA looks at the problem differently. If we wanted to find the highest peak in a range of mountains, then visiting every mountain takes too long, so a GA uses a targetted approach. I.E. You guess a local peak to begin with. It probably isn't the highest peak, so you guess again. Then using a chromosome/gene model borrowed from biology, where you have survival of the fittest, you match the good parameters of the mountains and keep going. Essentially you keep going, at every generation, the fittest members survive to keep going, until you can make no more "reasonable" improvement. I.E. Your solution evolves to find the best answer just like life on earth. What's happening is your taking spot readings over the range and homing in on the highest mountain.

A GA has a fitness function (in this case the height of the mountain), in the case of trading, it's your goal. The GA is a tool to help us fit the curve. A brute force method can be better than a GA, but if a GA doesn't reach the correct answer, it will likely reach one that's close. I.E. In the trade off between brute force and a GA, GA is really only the practical way to go, although brute force may be occasionally a little more superior in result.

So lets try some examples of incorrectly curve fitting with a few examples.

CURVE FITTING WITH TOO LITTLE DATA:

So we toss some coins. Coins can be heads or tails and our goal is to build a perfect coin toss predictor. We toss 3 times, and get heads each time. Therefore we optimize our solution, and build a perfect coin tosser that always generates heads as the answer. So what's wrong?

Well, our curve is heads/tails, but we took such a small sample (of size 3), that we didn't see the real picture. I.E. We tried to fit a curve where we couldn't see the whole curve. In trading, this is a classic mistake that is commonly made. We genetically optimize with not enough data. Remember from before that to be reasonably confident that we haven't incorrectly curve fitted the data, we need 30 trades per degree of freedom (DOF) for every variable in the model.

This shows up as, building a model that optimizes well, then trades poorly in real time. If you tested with adequate data, you'd have found out that it really was poor in the first place.

CURVE FITTING BY SELECTION: STOCK PICKING

We can also incorrectly curve fit by picking results, without even using a GA.

For instance, if you were to trade say 10 stocks randomly for a period of time, you'd likely make money on some and lose money on others. Just like tossing a coin would produce heads and tails.

So you have your perfect model and you want to trade, but it works on some stocks not others, so you plug in 100 stocks to find out which ones do well and which ones do poorly, and keep the good ones. Well you've just incorrectly curve fitted by another means. (or another way of looking at it is rendered your out of sample to be in sample). This is because out of any population (the 100), if you pick and choose your sample (the good ones), then your sample is no longer truely representative of your population.

CURVE FITTING BY SELECTION: INDICATORS

So, instead of picking the best stocks to use in your model, you pick the best indicators, i.e. just keep plugging at it until you find indicators that work.
Again, just another form of incorrect curve fitting for the same reason as the last.

CURVE FITTING BY SELECTION: PICKING THE BEST RESULTS

So you keep trying models until you find the best one. Again, just incorrectly curve fitting.

As you can see, this is a huge problem, there are so many ways to incorrectly curve fit. Anywhere where you pick and choose, or try different things open you up to curve fitting.

One solution might be to create another out of sample testing to get around the problem. But again, if you pick and choose between those out of samples, you're opening yourself up to the same problem again.

So, incorrectly curve fitting is not 100% avoidable, but needs to be realized and managed. Personally I follow this method to avoid it as much as possible:

1. Never try things out in a model in an untargetted approach, and this is where these threads about design models come into the picture. Start off with a goal, and design a model to fit that goal, don't just guess at methods or indicators that will work, start off with solid design from the ground up.

2. Use a GA to improve good models, not to make bad models work.

3. If using a GA, use it at the end of the process, i.e. as a final improvement to an already good model.

4. Use sufficient data to test with.

5. Always keep additional out of samples to test on. A good out of sample is always paper trading.

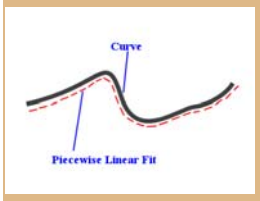
6. Never pick and choose results, stocks or anything else. (At least not without being aware of it and knowing the effect).

7. Keep degrees of freedom low. I.E. The smaller the DOF, the less data you need to validate which makes everything a lot simpler to test.

USING CURVE FITTING TO ADVANTAGE:

There is another way to approach curve fitting and make it work to your advantage. At first it seems like a crazy approach, but there are good reasons why it works. That is to keep DOF small and optimize frequently.

The reason for this is because of the curve fitting. Normally we wish to fit that curve perfectly, however, any curve can be approximated by a series of small lines. This is called a Piecewise Linear Approach. Linear = Line, Piecewise means small pieces.



I.E. If you keep Degrees Of Freedom (DOF) low so that your fit can be validated in minimal time, i.e. you're creating a small line, then it can fit (approximately) the curve of your function for a small period of time. You then reoptimize frequently to get additional small segments of lines.

Date :12/5/2005 11:04:28 AM Poster : Stephen

Mark,
Thanks for putting the chart on the web. I downloaded the chart and looked over the trading system. In the chart you used 4 different alpha values, two for the long side, and two for the short side. Shouldn't the alpha for the the trigger be the same as the indicator? This would give you 2 alphas and cut down the degrees of freedom. Looking through the code in Ehlers book I see that he always used the same alpha for the indicator and trigger. Can you explain the use of two different alphas (different alpha in trigger) in a cross over system? How does this avoid curve fitting? - Stephen

On 11/30/2005 7:59:03 PM Steve Eberbach wrote:
Also, I prefer 100*(ln(DJI-C)-ln(lag(DJI-C),1)), since it translates changes into a "reversible" percent change indicator. By that I mean if you accumulate these changes you restore the correct shape of the logarithmic price, on a percentage return basis, even if you go back and forth between changes and integrated (cumulative) changes many times, which does not happen if you use the standard "percent change" definition.

The standard percent change definition is fatally flawed. It will ruin your predictions, with a bias which makes a rise of 100 percent change equal to a decline of 50 percent change!

Steve

On 11/29/2005 7:36:29 AM Sunny wrote:
Steve,

Thank you for your thorough description.

I tried several different variation; however, there is something that I am doing wrong, and I would like to check with you on what I am doing:

Non-normalized

DJI-C

Lag(DJI-C, 40)

StndDev(ln(DJI-C) - lag(ln(DJI-C),1), 40)

StndDev(ln(DJI-C) - lag(ln(DJI-C),40), 40)

Normalized

ln(DJI-C) - lag(ln(DJI-C),1)

ln(DJI-C) - lag(ln(DJI-C),40)

StndNormalZScore(ln(DJI-C) - lag(ln(DJI-C),40),40)

StndNormalZScore(ln(DJI-C) - lag(ln(DJI-C),1), 40)

The normalized inputs are placed in a prediction.

I predicted the percentage change in the open.
The number of trading days into the prediction from the next open were 4.
I tried this both with optimization and without it.
I tried 4-walkforwards of 3-months.
I chose both long and short positions.
I used the trading rules greater than or less than zero.
The training objective was to maximize winners – losers.
The maximum training set size was 5 years.
The minimum training set size was 4 years.
Maximum number of hidden neurons during training were 80

The results that I got were not very good so I am sure that I did not follow your ideas correctly, but I am not sure where I am messing this up.

Regards,

Sunny

Sunny:

What I use is a spreadsheet called WaveWi$e to convert my files to log-normalized format, and Z-scores for the log normalized version of the data. This I do because I use very long data sets for stocks which range over 50 years' time to find the cycles which have persisted the longest time first, or even more relevantly, the cycles and correlations which have "always" made a comeback even if they almost disappear for a while. When run through the nets, if the neural net's lookback window is different from the one I chose, there will be a doubly applied z-score normalization.

I append an abbreviation, such as "Z40" to, for example, DJICLOSE, to indicate the input dow jones industrials close, z-score of a 40 bar moving window. I also keep the standard deviation associated with that 40 bar window, which is otherwise discarded information when just normalizing by z-score. That standard deviation represents the average variance from the 40 bar moving average, the average amplitude of variance from that moving average. The z-score represents "how many" of these standard average variances (differences squared) the present bar's value is from the moving average at the present bar. If both the z-score and the associated 40 bar standard deviation are available to the neural net as choices for input, then the neural net can "decide" if the local (40 bar) variance has any modulating effect on the significance of the normalized input, the z-score.

So, in the case of Steve Ward's add-ons or the prediction wizard, you would add another input, "DJICLOSESD40" if your window length, the "look back length" was 40 bars, along with the existing input, "DJICLOSE" which was normalized with the lookback window size, 40 bars, to give your network information of local volatility from which that normalization was automatically derived by the network's normalizer. So besides normalization "across inputs" as Steve points out, you also have normalization "across time intervals".

Steve

On 11/25/2005 4:49:15 PM Steve ward wrote:
The Prediction Wizard always uses z-score, as do the add-ons AT2 and NI. ANI, however, has no normalization across inputs, so only there is it really necessary to normalize across inputs. Normalization over time (detrending) is really where you need to be careful. Use indicators that are already normalized (like RSI, etc) or if using raw prices, then use change, percent change, spread from a moving average or index, etc.

On 11/22/2005 12:39:52 PM Steve Eberbach wrote:
Hi Mark: It is for this reason (changing volatility) that I have always converted all my indicators into moving z-score plus standard deviation (two variables). That way I have the inputs I need to test if there is useful information in the changes of volatility of each input. Another benefit of z-score is that the numeric indicators are nicely normalized, making it easier for me to read all my charts, since then I can put several indicators of different colors on one chart without severe vertical axis scaling problems which arise when trying to draw comparative charts.

Since Steve has written normalization into the neural nets, maybe he could include an option to simply display the input indicators as normalized for the prediction wizard, wherever these are in the memory, whether it is plus-minus a range, or z-score, or something else.

On 11/20/2005 3:00:07 PM Mark Simpson wrote:
Hi Dan,

First of all, you're not using an out of sample test as such, because the optimization date range is the same as the paper trading date range. Though this isn't causing the flat spot, it doesn't provide validation of the model either. I.E. you're validating the performance of the model with exactly the same data you're curve fitting the model to work best with. In NST you can seperate out the paper trading date range from the optimization range. However when you do that, you'll see the model doesn't perform too well anymore.

Regarding the flat spot. As Steve said, the market dynamics have changed. If you put a volatility indicator on that same chart, you'll see that around the beginning of 2003, volatility significantly dropped. The model worked well in a high volatility situation but not in a low volatility situation. Unfortunately, the DOF issue precludes you from producing a new model yet, i.e. you don't have enough recent data.

Assuming the model did successfully validate in paper trading at some point in time, then the only other way around the change in market this would be to normalize time, i.e. change the underlying data, this would produce volatility which was consistant and indicators which were "better behaved".

It's difficult to provide exact reasons without seeing the model, however these are some
points:

1. You mention that the equity curve is good at the beginning and flat at the end. That suggests
that you're running the GA on a certain period of time, and your "out of sample" is recent (presumably the flat part). A GA will generally do a good job of curve fitting because that's what it's
designed to do. So the "out of sample" (provided you haven't curve fitted by manually curve fitting, i.e. stock selection etc.) becomes the measurement of how well your model is working.
I.E. If you've validated with enough trades for the DOF and the out of sample is poor, then the model more than likely doesn't work, and the model needs refining or replacing.

The GA always tries to fit over the data you provide it, i.e. if you use the GA over 8 years, then
the results should be fairly consistant during that time (provided the market has the opportunity to make money). Which is why you need the out of sample to validate it.

2. Regarding DOF, you can't really cheat as such. However you can make better indicators that
have fewer DOF. It's feasible to build an indicator (assuming the 2 indicators you are using are the same in the short and long), such that you have 2 indicators for long and short with a 3rd
variable which essentially determines essentially becomes the adaption between short and long, that would give you 3 DOF and save 1 DOF, as currently you have duplication of information,
essentially you're removing correlated information by removing that 1 DOF.

If you can get DOF really low, i.e. 1 DOF (maybe 2), then you can get into piecewise linear approach of curve fitting (you still need to at least validate on an out of sample, until you're happy
the model works).

3. Also watch out for lag. I get the impression (although you don't explicitly say), that you're
using lagging indicators.

If possible, post your model to the forum, and we can take a further look at it.

Hi Dan,

DOF means a lot of different things to different people, however the way I approach
it is as follows.

To me a degree of freedom is an item that can change in a model. This could be:
1. A parameter to an indicator
2. Choice of indicator
3. Choice of security

All this is pretty vague, so hopefully the following examples will clarify it:

Model Inputs: RSI(x) on 1 security where x is optimized.
Answer: 1 DOF as x is a variable parameter i.e. it can change.

Model Inputs: RSI(5) on 1 security.
Answer: 1 DOF (as you need to validate the model on something).

Model Inputs: MACD(close,12,26) on 1 security
Answer: 1 DOF (as you need to validate the model on something).

Model Inputs: MACD(close,x,y) on 1 security where x/y are optimized.
Answer: 2 DOF (x and y)

Model Inputs: MACD(RSI (z), x, y) on 1 security where z/x/y are optimized.
Answer: 3 DOF (x, y and z)

Model Inputs: MACD (RSI (z), x, y) where z/x/y are optimized, and then we try
different stocks against it to find which ones perform best.
Answer: 4 DOF (x,y,z and stock selection)

Model Inputs: Indicator(x) where x is optimized, and we try many different indicators
to find one that works on 1 security.
Answer: 2 DOF (x and Indicator selection)

Model Inputs: MACD(close,5,20) where we just guessed 5,20 as being the parameters
on 1 security.
Answer: 1 DOF (as you need to validate the model on something)

Model Inputs: MACD(close,5,20) however, we tried many different values for 5 and 20 until we found the ones that worked on 1 security.
Answer: 2 DOF (becuase you were manually changing both the 5 and 20).

So if you let the optimizer choose a value, 1 DOF gets added. If you
manually choose a value through experimentation, 1 DOF gets added.

Steve,

Thank you for your thorough description.

I tried several different variation; however, there is something that I am doing wrong, and I would like to check with you on what I am doing:

Non-normalized

DJI-C

Lag(DJI-C, 40)

StndDev(ln(DJI-C) - lag(ln(DJI-C),1), 40)

StndDev(ln(DJI-C) - lag(ln(DJI-C),40), 40)

Normalized

ln(DJI-C) - lag(ln(DJI-C),1)

ln(DJI-C) - lag(ln(DJI-C),40)

StndNormalZScore(ln(DJI-C) - lag(ln(DJI-C),40),40)

StndNormalZScore(ln(DJI-C) - lag(ln(DJI-C),1), 40)

The normalized inputs are placed in a prediction.

I predicted the percentage change in the open.
The number of trading days into the prediction from the next open were 4.
I tried this both with optimization and without it.
I tried 4-walkforwards of 3-months.
I chose both long and short positions.
I used the trading rules greater than or less than zero.
The training objective was to maximize winners – losers.
The maximum training set size was 5 years.
The minimum training set size was 4 years.
Maximum number of hidden neurons during training were 80

The results that I got were not very good so I am sure that I did not follow your ideas correctly, but I am not sure where I am messing this up.

Sunny:

What I use is a spreadsheet called WaveWi$e to convert my files to log-normalized format, and Z-scores for the log normalized version of the data. This I do because I use very long data sets for stocks which range over 50 years' time to find the cycles which have persisted the longest time first, or even more relevantly, the cycles and correlations which have "always" made a comeback even if they almost disappear for a while. When run through the nets, if the neural net's lookback window is different from the one I chose, there will be a doubly applied z-score normalization.

I append an abbreviation, such as "Z40" to, for example, DJICLOSE, to indicate the input dow jones industrials close, z-score of a 40 bar moving window. I also keep the standard deviation associated with that 40 bar window, which is otherwise discarded information when just normalizing by z-score. That standard deviation represents the average variance from the 40 bar moving average, the average amplitude of variance from that moving average. The z-score represents "how many" of these standard average variances (differences squared) the present bar's value is from the moving average at the present bar. If both the z-score and the associated 40 bar standard deviation are available to the neural net as choices for input, then the neural net can "decide" if the local (40 bar) variance has any modulating effect on the significance of the normalized input, the z-score.

So, in the case of Steve Ward's add-ons or the prediction wizard, you would add another input, "DJICLOSESD40" if your window length, the "look back length" was 40 bars, along with the existing input, "DJICLOSE" which was normalized with the lookback window size, 40 bars, to give your network information of local volatility from which that normalization was automatically derived by the network's normalizer. So besides normalization "across inputs" as Steve points out, you also have normalization "across time intervals".

Hi Dan,

First of all, you're not using an out of sample test as such, because the optimization date range is the same as the paper trading date range. Though this isn't causing the flat spot, it doesn't provide validation of the model either. I.E. you're validating the performance of the model with exactly the same data you're curve fitting the model to work best with. In NST you can seperate out the paper trading dale range from the optimization range. However when you do that, you'll see the model doesn't perform too well anymore.

Regarding the flat spot. As Steve said, the market dynamics have changed. If you put a volatility indicator on that same chart, you'll see that around the beginning of 2003, volatility significantly dropped. The model worked well in a high volatility situation but not in a low volatility situation. Unfortunately, the DOF issue precludes you from producing a new model yet, i.e. you don't have enough recent data.

Assuming the model did successfully validate in paper trading at some point in time, then the only other way around the change in market this would be to normalize time, i.e. change the underlying data, this would produce volatility which was consistant and indicators which were "better behaved".

It's difficult to provide exact reasons without seeing the model, however these are some points:

1. You mention that the equity curve is good at the beginning and flat at the end. That suggests that you're running the GA on a certain period of time, and your "out of sample" is recent (presumably the flat part). A GA wil generally do a good job of curve fitting because that's what it's designed to do. So the "out of sample" (provided you haven't curve fitted by manually curve fitting, i.e. stock selection etc.) becomes the measurement of how well your model is working.
I.E. If you've validated with enough trades for the DOF and the out of sample is poor, then the model more than likely doesn't work, and the model needs refining or replacing.

The GA always tries to fit over the data you provide it, i.e. if you use the GA over 8 years, then the results should be fairly consistant during that time (provided the market has the opportunity to make money). Which is why you need the out of sample to validate it.

2. Regarding DOF, you can't really cheat as such. However you can make better indicators that have fewer DOF. It's feasible to build an indicator (assuming the 2 indicators you are using are the same in the short and long), such that you have 2 indicators for long and short with a 3rd variable which essentially determines essentially becomes the adaption between short and long, that would give you 3 DOF and save 1 DOF, as currently you have duplication of information, essentially you're removing correlated information by removing that 1 DOF.

If you can get DOF really low, i.e. 1 DOF (maybe 2), then you can get into piecewise linear approach of curve fitting (you still need to at least validate on an out of sample, until you're happy the model works).

3. Also watch out for lag. I get the impression (although you don't explicitly say), that you're using lagging indicators.

If possible, post your model to the forum, and we can take a further look at it.

Hi Dan,

DOF means a lot of different things to different people, however the way I approach it is as follows.

To me a degree of freedom is an item that can change in a model. This could be:
1. A parameter to an indicator
2. Choice of indicator
3. Choice of security

All this is pretty vague, so hopefully the following examples will clarify it:

Model Inputs: RSI(x) on 1 security where x is optimized.
Answer: 1 DOF as x is a variable parameter i.e. it can change.

Model Inputs: RSI(5) on 1 security.
Answer: 1 DOF (as you need to validate the model on something).

Model Inputs: MACD(close,12,26) on 1 security
Answer: 1 DOF (as you need to validate the model on something).

Model Inputs: MACD(close,x,y) on 1 security where x/y are optimized.
Answer: 2 DOF (x and y)

Model Inputs: MACD(RSI (z), x, y) on 1 security where z/x/y are optimized.
Answer: 3 DOF (x, y and z)

Model Inputs: MACD (RSI (z), x, y) where z/x/y are optimized, and then we try
different stocks against it to find which ones perform best.
Answer: 4 DOF (x,y,z and stock selection)

Model Inputs: Indicator(x) where x is optimized, and we try many different indicators
to find one that works on 1 security.
Answer: 2 DOF (x and Indicator selection)

Model Inputs: MACD(close,5,20) where we just guessed 5,20 as being the parameters
on 1 security.
Answer: 1 DOF (as you need to validate the model on something)

Model Inputs: MACD(close,5,20) however, we tried many different values for 5 and 20 until we found the ones that worked on 1 security.
Answer: 2 DOF (becuase you were manually changing both the 5 and 20).

So if you let the optimizer choose a value, 1 DOF gets added. If you
manually choose a value through experimentation, 1 DOF gets added.

On 8/30/2005 2:24:54 PM Mark Simpson wrote:
This thread is about curve fitting. I also refer you to Steve Ward's tips on preventing
over-optimization http://www.ward.net/cgi-bin/viewtip.asp?ID=105 as a guideline for
what you can do to avoid it.

So, lets start off with what a GA (Genetic Algorithm) is, to remove some of the mysticism behind the GA built into Neuroshell. Personally I believe that it's
by understanding the principles of this that it can be better used to advantage.
The GA is a very powerful tool if used correctly, if used incorrectly it can sink
you.

You've probably come across the following problem, you build your
system, keep optimizing various types of system until you find one that does well,
then you trade it in realtime, and poof, that well performing system eats you alive.
If you've done everything else correctly, i.e. tested on out samples and used walk forwards, then the chances are you've just incorrectly curve fitted without realizing it.

So what is curve fitting? If you imagine your trading system like this, you
have inputs and you have an output (trading signals). You have a black box in the middle which translates between. Essentially the output is a function
of the input. I.E. Output=f (Input1..Input N)

The output is the curve, i.e. it's a varying function, and the idea is that we have to
design the function so that it fits that curve.

So, lets translate this to the NST world. We use a bunch of indicators to go into
our "function", and then see how well the function works (performance). However
it doesn't do too well, so we use the optimization feature in NST (a GA) to alter
the parameters to the indicators to make the function fit the curve better.

A Genetic Algorithm (GA) is just a tool to reduce the search space. For instance
if you had 5 indicators with a total of 10 possible parameters, then to try every
possible combination would take a long time. Trying every possibility is a brute force
method and isn't practical unless your model is extremely simple.

A GA looks at the problem differently. If we wanted to find the highest peak in a range of mountains, then visiting every mountain takes too long, so a GA
uses a targetted approach. I.E. You guess a local peak to begin with. It probably
isn't the highest peak, so you guess again. Then using a chromosome/gene
model borrowed from biology, where you have survival of the fittest, you match the good parameters of the mountains and keep going. Essentially you keep going, at every
generation, the fittest members survive to keep going, until you can make no more "reasonable" improvement. I.E. Your solution evolves to find the best answer
just like life on earth. What's happening is your taking spot readings over the range
and homing in on the highest mountain.

A GA has a fitness function (in this case the height of the mountain), in the case of
trading, it's your goal. The GA is a tool to help us fit the curve. A brute force method can be better than a GA, but if a GA doesn't reach the correct answer, it will likely
reach one that's close. I.E. In the trade off between brute force and a GA, GA is
really only the practical way to go, although brute force may be occasionally a little
more superior in result.

So lets try some examples of incorrectly curve fitting with a few examples.

CURVE FITTING WITH TOO LITTLE DATA:

So we toss some coins. Coins can be heads or tails and our goal is to build a perfect
coin toss predictor. We toss 3 times, and get heads each time. Therefore we
optimize our solution, and build a perfect coin tosser that always generates heads
as the answer. So what's wrong?

Well, our curve is heads/tails, but we took such a small sample (of size 3), that
we didn't see the real picture. I.E. We tried to fit a curve where we couldn't see the whole curve. In trading, this is a classic mistake that is commonly made. We genetically
optimize with not enough data. Remember from before that to be
reasonably confident that we haven't incorrectly curve fitted the data, we need
30 trades per degree of freedom (DOF) for every variable in the model.

This shows up as, building a model that optimizes well, then trades poorly in real time.
If you tested with adequate data, you'd have found out that it really was poor in the
first place.

CURVE FITTING BY SELECTION: STOCK PICKING

We can also incorrectly curve fit by picking results, without even using a GA.

For instance, if you were to trade say 10 stocks randomly for a period of time,
you'd likely make money on some and lose money on others. Just like tossing
a coin would produce heads and tails.

So you have your perfect model and you want to trade, but it works on some stocks
not others, so you plug in 100 stocks to find out which ones do well and which ones
do poorly, and keep the good ones. Well you've just incorrectly curve fitted by
another means. (or another way of looking at it is rendered your out of sample to be in sample). This is because out of any population (the 100), if you pick and choose your
sample (the good ones), then your sample is no longer truely representative of your population.

CURVE FITTING BY SELECTION: INDICATORS

So, instead of picking the best stocks to use in your model, you pick the best indicators, i.e. just keep plugging at it until you find indicators that work.
Again, just another form of incorrect curve fitting for the same reason as the
last.

CURVE FITTING BY SELECTION: PICKING THE BEST RESULTS

So you keep trying models until you find the best one. Again, just incorrectly curve fitting.

As you can see, this is a huge problem, there are so many ways to incorrectly
curve fit. Anywhere where you pick and choose, or try different things open you
up to curve fitting.

One solution might be to create another out of sample testing to get around the problem. But again, if you pick and choose between those out of samples, you're
opening yourself up to the same problem again.

So, incorrectly curve fitting is not 100% avoidable, but needs to be realized and
managed. Personally I follow this method to avoid it as much as possible:

1. Never try things out in a model in an untargetted approach, and
this is where these threads about design models come into the picture. Start off
with a goal, and design a model to fit that goal, don't just guess at methods or
indicators that will work, start off with solid design from the ground up.

2. Use a GA to improve good models, not to make bad models work.

3. If using a GA, use it at the end of the process, i.e. as a final improvement to an
already good model.

4. Use sufficient data to test with.

5. Always keep additional out of samples to test on. A good out of sample is
always paper trading.

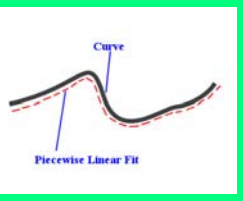
6. Never pick and choose results, stocks or anything else. (At least not without
being aware of it and knowing the effect).

7. Keep degrees of freedom low. I.E. The smaller the DOF, the less data you
need to validate which makes everything a lot simpler to test.

USING CURVE FITTING TO ADVANTAGE:

There is another way to approach curve fitting and make it work to your advantage. At first it seems like a crazy approach, but there are good reasons why it works. That is to keep DOF small and optimize frequently.

The reason for this is because of the curve fitting. Normally we wish to fit that curve perfectly, however, any curve can be approximated by a series of small lines. This is called a Piecewise Linear Approach. Linear = Line, Piecewise means small pieces.



I.E. If you keep Degrees Of Freedom (DOF) low so that your fit can be validated in minimal time, i.e. you're creating a small line, then it can fit (approximately) the curve of your function for a small period of time. You then reoptimize frequently to get additional small segments of lines.

Postcript-Re: Curve fitting. What it is, how to avoid it and how to use it to advantage

Date :12/5/2005 8:55:22 PM Poster : Dan Melton

Hi Stephen,

The chart you're referring to is simply the "out of the box" Adaptive RVI template that comes with the Cybernetic Indicators. The point of the post really was the problem of the flattened equity curve, which seems to be popping up in several systems I'm experimenting with. My hope was to find a fix that would cause GA to somehow give preference to solutions with an equity curve that was steeper toward the end. Instead, the benefit of the optimization seems to be weighted toward the beginning of the curve. (Mark pointed out that a major shift in volatility seems to contribute here.)

As to linking the alpha parameters: if that is so (i.e. they should be linked), it doesn't appear to be present in the template. Makes sense, though. Thanks for the thought!

Mark,
Thanks for putting the chart on the web. I downloaded the chart and looked over the trading system. In the chart you used 4 different alpha values, two for the long side, and two for the short side. Shouldn't the alpha for the the trigger be the same as the indicator? This would give you 2 alphas and cut down the degrees of freedom. Looking through the code in EINers book I see that he always used the same alpha for the indicator and trigger. Can you explain the use of two different alphas (different alpha in trigger) in a cross over system? How does this avoid curve fitting? - Stephen

It's difficult to provide exact reasons without seeing the model, however these are some points:

1. You mention that the equity curve is good at the beginning and flat at the end. That suggests that you're running the GA on a certain period of time, and your "out of sample" is recent (presumably the flat part). A GA will generally do a good job of curve fitting because that's what it's designed to do. So the "out of sample" (provided you haven't curve fitted by manually curve fitting, i.e. stock selection etc.) becomes the measurement of how well your model is working.
I.E. If you've validated with enough trades for the DOF and the out of sample is poor, then the model more than likely doesn't work, and the model needs refining or replacing.

The GA always tries to fit over the data you provide it, i.e. if you use the GA over 8 years, then the results should be fairly consistant during that time (provided the market has the opportunity to make money). Which is why you need the out of sample to validate it.

2. Regarding DOF, you can't really cheat as such. However you can make better indicators that have fewer DOF. It's feasible to build an indicator (assuming the 2 indicators you are using are the same in the short and long), such that you have 2 indicators for long and short with a 3rd variable which essentially determines essentially becomes the adaption between short and long, that would give you 3 DOF and save 1 DOF, as currently you have duplication of information, essentially you're removing correlated information by removing that 1 DOF.

If you can get DOF really low, i.e. 1 DOF (maybe 2), then you can get into piecewise linear approach of curve fitting (you still need to at least validate on an out of sample, until you're happy the model works).

3. Also watch out for lag. I get the impression (although you don't explicitly say), that you're using lagging indicators.

If possible, post your model to the forum, and we can take a further look at it.

Hi Dan,

DOF means a lot of different things to different people, however the way I approach it is as follows.

To me a degree of freedom is an item that can change in a model. This could be:
1. A parameter to an indicator
2. Choice of indicator
3. Choice of security

All this is pretty vague, so hopefully the following examples will clarify it:

Model Inputs: RSI(x) on 1 security where x is optimized.
Answer: 1 DOF as x is a variable parameter i.e. it can change.

Model Inputs: RSI(5) on 1 security.
Answer: 1 DOF (as you need to validate the model on something).

Model Inputs: MACD(close,12,26) on 1 security
Answer: 1 DOF (as you need to validate the model on something).

Model Inputs: MACD(close,x,y) on 1 security where x/y are optimized.
Answer: 2 DOF (x and y)

Model Inputs: MACD(RSI (z), x, y) on 1 security where z/x/y are optimized.
Answer: 3 DOF (x, y and z)

Model Inputs: MACD (RSI (z), x, y) where z/x/y are optimized, and then we try different stocks against it to find which ones perform best.
Answer: 4 DOF (x,y,z and stock selection)

Model Inputs: Indicator(x) where x is optimized, and we try many different indicators to find one that works on 1 security.
Answer: 2 DOF (x and Indicator selection)

Model Inputs: MACD(close,5,20) where we just guessed 5,20 as being the parameters on 1 security.
Answer: 1 DOF (as you need to validate the model on something)

Model Inputs: MACD(close,5,20) however, we tried many different values for 5 and 20 until we found the ones that worked on 1 security.
Answer: 2 DOF (becuase you were manually changing both the 5 and 20).

So if you let the optimizer choose a value, 1 DOF gets added. If you manually choose a value through experimentation, 1 DOF gets added.

This thread is about curve fitting. I also refer you to Steve Ward's tips on preventing over-optimization http://www.ward.net/cgi-bin/viewtip.asp?ID=105 as a guideline for what you can do to avoid it.

So, lets start off with what a GA (Genetic Algorithm) is, to remove some of the mysticism behind the GA built into Neuroshell. Personally I believe that it's by understanding the principles of this that it can be better used to advantage.
The GA is a very powerful tool if used correctly, if used incorrectly it can sink you.

You've probably come across the following problem, you build your system, keep optimizing various types of system until you find one that does well, then you trade it in realtime, and poof, that well performing system eats you alive.

If you've done everything else correctly, i.e. tested on out samples and used walk forwards, then the chances are you've just incorrectly curve fitted without realizing it.

So what is curve fitting? If you imagine your trading system like this, you
have inputs and you have an output (trading signals). You have a black box in the middle which translates between. Essentially the output is a function
of the input. I.E. Output=f (Input1..Input N)

The output is the curve, i.e. it's a varying function, and the idea is that we have to
design the function so that it fits that curve.

So, lets translate this to the NST world. We use a bunch of indicators to go into
our "function", and then see how well the function works (performance). However
it doesn't do too well, so we use the optimization feature in NST (a GA) to alter
the parameters to the indicators to make the function fit the curve better.

A Genetic Algorithm (GA) is just a tool to reduce the search space. For instance
if you had 5 indicators with a total of 10 possible parameters, then to try every
possible combination would take a long time. Trying every possibility is a brute force
method and isn't practical unless your model is extremely simple.

A GA looks at the problem differently. If we wanted to find the highest peak in a range of mountains, then visiting every mountain takes too long, so a GA
uses a targetted approach. I.E. You guess a local peak to begin with. It probably
isn't the highest peak, so you guess again. Then using a chromosome/gene
model borrowed from biology, where you have survival of the fittest, you match the good parameters of the mountains and keep going. Essentially you keep going, at every
generation, the fittest members survive to keep going, until you can make no more "reasonable" improvement. I.E. Your solution evolves to find the best answer
just like life on earth. What's happening is your taking spot readings over the range
and homing in on the highest mountain.

A GA has a fitness function (in this case the height of the mountain), in the case of
trading, it's your goal. The GA is a tool to help us fit the curve. A brute force method can be better than a GA, but if a GA doesn't reach the correct answer, it will likely
reach one that's close. I.E. In the trade off between brute force and a GA, GA is
really only the practical way to go, although brute force may be occasionally a little
more superior in result.

So lets try some examples of incorrectly curve fitting with a few examples.

CURVE FITTING WITH TOO LITTLE DATA:

So we toss some coins. Coins can be heads or tails and our goal is to build a perfect
coin toss predictor. We toss 3 times, and get heads each time. Therefore we
optimize our solution, and build a perfect coin tosser that always generates heads
as the answer. So what's wrong?

Well, our curve is heads/tails, but we took such a small sample (of size 3), that
we didn't see the real picture. I.E. We tried to fit a curve where we couldn't see the whole curve. In trading, this is a classic mistake that is commonly made. We genetically
optimize with not enough data. Remember from before that to be
reasonably confident that we haven't incorrectly curve fitted the data, we need
30 trades per degree of freedom (DOF) for every variable in the model.

This shows up as, building a model that optimizes well, then trades poorly in real time.
If you tested with adequate data, you'd have found out that it really was poor in the
first place.

CURVE FITTING BY SELECTION: STOCK PICKING

We can also incorrectly curve fit by picking results, without even using a GA.

For instance, if you were to trade say 10 stocks randomly for a period of time,
you'd likely make money on some and lose money on others. Just like tossing
a coin would produce heads and tails.

So you have your perfect model and you want to trade, but it works on some stocks
not others, so you plug in 100 stocks to find out which ones do well and which ones
do poorly, and keep the good ones. Well you've just incorrectly curve fitted by
another means. (or another way of looking at it is rendered your out of sample to be in sample). This is because out of any population (the 100), if you pick and choose your
sample (the good ones), then your sample is no longer truely representative of your population.

CURVE FITTING BY SELECTION: INDICATORS

So, instead of picking the best stocks to use in your model, you pick the best indicators, i.e. just keep plugging at it until you find indicators that work.
Again, just another form of incorrect curve fitting for the same reason as the
last.

CURVE FITTING BY SELECTION: PICKING THE BEST RESULTS

So you keep trying models until you find the best one. Again, just incorrectly curve fitting.

As you can see, this is a huge problem, there are so many ways to incorrectly
curve fit. Anywhere where you pick and choose, or try different things open you
up to curve fitting.

One solution might be to create another out of sample testing to get around the problem. But again, if you pick and choose between those out of samples, you're
opening yourself up to the same problem again.

So, incorrectly curve fitting is not 100% avoidable, but needs to be realized and
managed. Personally I follow this method to avoid it as much as possible:

1. Never try things out in a model in an untargetted approach, and
this is where these threads about design models come into the picture. Start off
with a goal, and design a model to fit that goal, don't just guess at methods or
indicators that will work, start off with solid design from the ground up.

2. Use a GA to improve good models, not to make bad models work.

3. If using a GA, use it at the end of the process, i.e. as a final improvement to an
already good model.

4. Use sufficient data to test with.

5. Always keep additional out of samples to test on. A good out of sample is
always paper trading.

6. Never pick and choose results, stocks or anything else. (At least not without
being aware of it and knowing the effect).

7. Keep degrees of freedom low. I.E. The smaller the DOF, the less data you
need to validate which makes everything a lot simpler to test.

USING CURVE FITTING TO ADVANTAGE:

There is another way to approach curve fitting and make it work to your advantage. At first it seems like a crazy approach, but there are good reasons why it works. That is to
keep DOF small and optimize frequently.

The reason for this is because of the curve fitting. Normally we wish to fit that curve perfectly, however, any curve can be approximated by a series of small lines. This is
called a Piecewise Linear Approach. Linear = Line, Piecewise means small pieces.

I.E. If you keep Degrees Of Freedom (DOF) low so that your fit can be validated in minimal time, i.e. you're creating a small line, then it can fit (approximately) the curve
of your function for a small period of time. You then reoptimize frequently to get additional small segments of lines.

Re: Curve fitting. What it is, how to avoid it and how to use it to advantage

Date :11/23/2005 3:33:58 PM Poster : Dan

Hi Mark--

Thanks for the warning on the in-sample data. I had hoped to resolve the equity flat spot, issue, tune up with some exits if possible (i.e. DOF limits), then move on to out of sample data. But I imagine that paper trading right away might not be a bad way to
immediately chuck the weak models!

What I'm getting from your post is: find another model! Probably good advice at this point. I guess the only other option is to follow Ward's example and perhaps optimize for a shorter period (i.e. post change in volatility patterns) but accumulate trades toward DOF guidelines by optimizing over indicators.

Thanks for taking the time to look at the model and posting--

Dan Melton

On 11/20/2005 3:00:07 PM Mark Simpson wrote:
Hi Dan,

First of all, you're not using an out of sample test as such, because the optimization date range is the same as the paper trading date range. Though this isn't causing the flat
spot, it doesn't provide validation of the model either. I.E. you're validating the performance of the model with exactly the same data you're curve fitting the model to work best with. In NST you can seperate out the paper trading date range from the optimization range. However when you do that, you'll see the model doesn't perform
too well anymore.

Regarding the flat spot. As Steve said, the market dynamics have changed. If
you put a volatility indicator on that same chart, you'll see that around the beginning of 2003, volatility significantly dropped. The model worked well in a high volatility situation but not in a low volatility situation. Unfortunately, the DOF issue precludes you from producing a new model yet, i.e. you don't have enough recent data.

Assuming the model did successfully validate in paper trading at some point in time,
then the only other way around the change in market this would be to normalize time,
i.e. change the underlying data, this would produce volatility which was consistant and indicators which were "better behaved".

Mark,

I'm attaching an example chart--a simple out-of-the-box crossover system from the Cybernetic Indicator add-on using Adaptive RVI. From here I sometimes elaborate with alternative exits and/or stops (results roughly similar). I'd also like to combine this with another system that kicks in when the market is trending as opposed to range-bound, but here is where I get into trouble in needing so many trades to account for the DOF for what is essentially two systems combined into one.

In case you don't have those indicators on your machine, I'm attaching a picture also (at least you can see the equity curve).

Thanks for any other thoughts you might have!

Hi Dan,

DOF means a lot of different things to different people, however the way I approach
it is as follows.

To me a degree of freedom is an item that can change in a model. This could be:
1. A parameter to an indicator
2. Choice of indicator
3. Choice of security

All this is pretty vague, so hopefully the following examples will clarify it:

Model Inputs: RSI(x) on 1 security where x is optimized.
Answer: 1 DOF as x is a variable parameter i.e. it can change.

Model Inputs: RSI(5) on 1 security.
Answer: 1 DOF (as you need to validate the model on something).

Model Inputs: MACD(close,12,26) on 1 security
Answer: 1 DOF (as you need to validate the model on something).

Model Inputs: MACD(close,x,y) on 1 security where x/y are optimized.
Answer: 2 DOF (x and y)

Model Inputs: MACD(RSI (z), x, y) on 1 security where z/x/y are optimized.
Answer: 3 DOF (x, y and z)

Model Inputs: MACD (RSI (z), x, y) where z/x/y are optimized, and then we try
different stocks against it to find which ones perform best.
Answer: 4 DOF (x,y,z and stock selection)

Model Inputs: Indicator(x) where x is optimized, and we try many different indicators
to find one that works on 1 security.
Answer: 2 DOF (x and Indicator selection)

Model Inputs: MACD(close,5,20) where we just guessed 5,20 as being the parameters
on 1 security.
Answer: 1 DOF (as you need to validate the model on something)

Model Inputs: MACD(close,5,20) however, we tried many different values for 5 and 20 until we found the ones that worked on 1 security.
Answer: 2 DOF (becuase you were manually changing both the 5 and 20).

So if you let the optimizer choose a value, 1 DOF gets added. If you
manually choose a value through experimentation, 1 DOF gets added.

Hi Dan,

First of all, you're not using an out of sample test as such, because the optimization date range is the same as the paper trading date range. Though this isn't causing the flat
spot, it doesn't provide validation of the model either. I.E. you're validating the performance of the model with exactly the same data you're curve fitting the model to work best with. In NST you can seperate out the paper trading date range from the
optimization range. However when you do that, you'll see the model doesn't perform
too well anymore.

Regarding the flat spot. As Steve said, the market dynamics have changed. If
you put a volatility indicator on that same chart, you'll see that around the beginning of 2003, volatility significantly dropped. The model worked well in a high volatility situation but not in a low volatility situation. Unfortunately, the DOF issue precludes
you from
producing a new model yet, i.e. you don't have enough recent data.

Assuming the model did successfully validate in paper trading at some point in time,
then the only other way around the change in market this would be to normalize time,
i.e. change the underlying data, this would produce volatility which was consistant and indicators which were "better behaved".

Mark,

I'm attaching an example chart--a simple out-of-the-box crossover system from the Cybernetic Indicator add-on using Adaptive RVI. From here I sometimes elaborate with alternative exits and/or stops (results roughly similar). I'd also like to combine
this with another system that kicks in when the market is trending as opposed to range-bound, but here is where I get into trouble in needing so many trades to account for the DOF for what is essentially two systems combined into one.

In case you don't have those indicators on your machine, I'm attaching a picture also (at least you can see the equity curve).

Thanks for any other thoughts you might have!

It's difficult to provide exact reasons without seeing the model, however these are some
points:

1. You mention that the equity curve is good at the beginning and flat at the end. That suggests
that you're running the GA on a certain period of time, and your "out of sample" is recent (presumably the flat part). A GA will generally do a good job of curve fitting because that's what it's designed to do. So the "out of sample" (provided you haven't
curve fitted by manually curve fitting, i.e. stock selection etc.) becomes the measurement of how well your model is working.
I.E. If you've validated with enough trades for the DOF and the out of sample is poor, then the model more than likely doesn't work, and the model needs refining or replacing.

The GA always tries to fit over the data you provide it, i.e. if you use the GA over 8 years, then
the results should be fairly consistant during that time (provided the market has the opportunity to make money). Which is why you need the out of sample to validate it.

2. Regarding DOF, you can't really cheat as such. However you can make better indicators that
have fewer DOF. It's feasible to build an indicator (assuming the 2 indicators you are using are the same in the short and long), such that you have 2 indicators for long and short with a 3rd variable which essentially determines essentially becomes
the adaption between short and long, that would give you 3 DOF and save 1 DOF, as currently you have duplication of information, essentially you're removing correlated information by removing that 1 DOF.

If you can get DOF really low, i.e. 1 DOF (maybe 2), then you can get into piecewise linear approach of curve fitting (you still need to at least validate on an out of sample, until you're happy the model works).

3. Also watch out for lag. I get the impression (although you don't explicitly say), that you're
using lagging indicators.

If possible, post your model to the forum, and we can take a further look at it.

Hi Dan,

DOF means a lot of different things to different people, however the way I approach
it is as follows.

To me a degree of freedom is an item that can change in a model. This could be:
1. A parameter to an indicator
2. Choice of indicator
3. Choice of security

All this is pretty vague, so hopefully the following examples will clarify it:

Model Inputs: RSI(x) on 1 security where x is optimized.
Answer: 1 DOF as x is a variable parameter i.e. it can change.

Model Inputs: RSI(5) on 1 security.
Answer: 1 DOF (as you need to validate the model on something).

Model Inputs: MACD(close,12,26) on 1 security
Answer: 1 DOF (as you need to validate the model on something).

Model Inputs: MACD(close,x,y) on 1 security where x/y are optimized.
Answer: 2 DOF (x and y)

Model Inputs: MACD(RSI (z), x, y) on 1 security where z/x/y are optimized.
Answer: 3 DOF (x, y and z)

Model Inputs: MACD (RSI (z), x, y) where z/x/y are optimized, and then we try
different stocks against it to find which ones perform best.
Answer: 4 DOF (x,y,z and stock selection)

Model Inputs: Indicator(x) where x is optimized, and we try many different indicators
to find one that works on 1 security.
Answer: 2 DOF (x and Indicator selection)

Model Inputs: MACD(close,5,20) where we just guessed 5,20 as being the parameters
on 1 security.
Answer: 1 DOF (as you need to validate the model on something)

Model Inputs: MACD(close,5,20) however, we tried many different values for 5 and 20 until we found the ones that worked on 1 security.
Answer: 2 DOF (becuase you were manually changing both the 5 and 20).

So if you let the optimizer choose a value, 1 DOF gets added. If you
manually choose a value through experimentation, 1 DOF gets added.

On 8/30/2005 2:24:54 PM Mark Simpson wrote:
This thread is about curve fitting. I also refer you to Steve Ward's tips on preventing
over-optimization http://www.ward.net/cgi-bin/viewtip.asp?ID=105 as a guideline for
what you can do to avoid it.

So, lets start off with what a GA (Genetic Algorithm) is, to remove some of the mysticism behind the GA built into Neuroshell. Personally I believe that it's
by understanding the principles of this that it can be better used to advantage.
The GA is a very powerful tool if used correctly, if used incorrectly it can sink
you.

You've probably come across the following problem, you build your
system, keep optimizing various types of system until you find one that does well,
then you trade it in realtime, and poof, that well performing system eats you alive.
If you've done everything else correctly, i.e. tested on out samples and used walk forwards, then the chances are you've just incorrectly curve fitted without realizing it.

So what is curve fitting? If you imagine your trading system like this, you
have inputs and you have an output (trading signals). You have a black box in the middle which translates between. Essentially the output is a function
of the input. I.E. Output=f (Input1..Input N)

The output is the curve, i.e. it's a varying function, and the idea is that we have to
design the function so that it fits that curve.

So, lets translate this to the NST world. We use a bunch of indicators to go into
our "function", and then see how well the function works (performance). However
it doesn't do too well, so we use the optimization feature in NST (a GA) to alter

the parameters to the indicators to make the function fit the curve better.

A Genetic Algorithm (GA) is just a tool to reduce the search space. For instance
if you had 5 indicators with a total of 10 possible parameters, then to try every
possible combination would take a long time. Trying every possibility is a brute force
method and isn't practical unless your model is extremely simple.

A GA looks at the problem differently. If we wanted to find the highest peak in a range of mountains, then visiting every mountain takes too long, so a GA
uses a targetted approach. I.E. You guess a local peak to begin with. It probably
isn't the highest peak, so you guess again. Then using a chromosome/gene
model borrowed from biology, where you have survival of the fittest, you match the good parameters of the mountains and keep going. Essentially you keep going, at every generation, the fittest members survive to keep going, until you can make no
more "reasonable" improvement. I.E. Your solution evolves to find the best answer
just like life on earth. What's happening is your taking spot readings over the range
and homing in on the highest mountain.

A GA has a fitness function (in this case the height of the mountain), in the case of
trading, it's your goal. The GA is a tool to help us fit the curve. A brute force method can be better than a GA, but if a GA doesn't reach the correct answer, it will likely
reach one that's close. I.E. In the trade off between brute force and a GA, GA is
really only the practical way to go, although brute force may be occasionally a little
more superior in result.

So lets try some examples of incorrectly curve fitting with a few examples.

CURVE FITTING WITH TOO LITTLE DATA:

So we toss some coins. Coins can be heads or tails and our goal is to build a perfect
coin toss predictor. We toss 3 times, and get heads each time. Therefore we
optimize our solution, and build a perfect coin tosser that always generates heads
as the answer. So what's wrong?

Well, our curve is heads/tails, but we took such a small sample (of size 3), that
we didn't see the real picture. I.E. We tried to fit a curve where we couldn't see the whole curve. In trading, this is a classic mistake that is commonly made. We genetically optimize with not enough data. Remember from before that to be
reasonably confident that we haven't incorrectly curve fitted the data, we need
30 trades per degree of freedom (DOF) for every variable in the model.

This shows up as, building a model that optimizes well, then trades poorly in real time.
If you tested with adequate data, you'd have found out that it really was poor in the
first place.

CURVE FITTING BY SELECTION: STOCK PICKING

We can also incorrectly curve fit by picking results, without even using a GA.

For instance, if you were to trade say 10 stocks randomly for a period of time,
you'd likely make money on some and lose money on others. Just like tossing
a coin would produce heads and tails.

So you have your perfect model and you want to trade, but it works on some stocks
not others, so you plug in 100 stocks to find out which ones do well and which ones
do poorly, and keep the good ones. Well you've just incorrectly curve fitted by
another means. (or another way of looking at it is rendered your out of sample to be in sample). This is because out of any population (the 100), if you pick and choose your sample (the good ones), then your sample is no longer truely representative
of your population.

CURVE FITTING BY SELECTION: INDICATORS

So, instead of picking the best stocks to use in your model, you pick the best indicators, i.e. just keep plugging at it until you find indicators that work.
Again, just another form of incorrect curve fitting for the same reason as the
last.

CURVE FITTING BY SELECTION: PICKING THE BEST RESULTS

So you keep trying models until you find the best one. Again, just incorrectly curve fitting.

As you can see, this is a huge problem, there are so many ways to incorrectly
curve fit. Anywhere where you pick and choose, or try different things open you
up to curve fitting.

One solution might be to create another out of sample testing to get around the problem. But again, if you pick and choose between those out of samples, you're
opening yourself up to the same problem again.

So, incorrectly curve fitting is not 100% avoidable, but needs to be realized and
managed. Personally I follow this method to avoid it as much as possible:

1. Never try things out in a model in an untargetted approach, and
this is where these threads about design models come into the picture. Start off
with a goal, and design a model to fit that goal, don't just guess at methods or
indicators that will work, start off with solid design from the ground up.

2. Use a GA to improve good models, not to make bad models work.

3. If using a GA, use it at the end of the process, i.e. as a final improvement to an
already good model.

4. Use sufficient data to test with.

5. Always keep additional out of samples to test on. A good out of sample is
always paper trading.

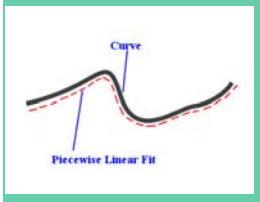
6. Never pick and choose results, stocks or anything else. (At least not without
being aware of it and knowing the effect).

7. Keep degrees of freedom low. I.E. The smaller the DOF, the less data you
need to validate which makes everything a lot simpler to test.

USING CURVE FITTING TO ADVANTAGE:

There is another way to approach curve fitting and make it work to your advantage. At first it seems like a crazy approach, but there are good reasons why it works. That is to keep DOF small and optimize frequently.

The reason for this is because of the curve fitting. Normally we wish to fit that curve perfectly, however, any curve can be approximated by a series of small lines. This is
called a Piecewise Linear Approach. Linear = Line, Piecewise means small pieces.



I.E. If you keep Degrees Of Freedom (DOF) low so that your fit can be validated in minimal time, i.e. you're creating a small line, then it can fit (approximately) the curve
of your function for a small period of time. You then reoptimize frequently to get additional small segments of lines.

Re: Curve fitting. What it is, how to avoid it and how to use it to advantage

Date :11/14/2005 3:05:03 PM Poster : Ward.net Webmaster

If it is any consolation, this is happening on our models too, and those of other users we've talked to. 2005 has been a really hard year for models, because the great patterns of 2001-2003 aren't there any longer (2004 was a transition we think). We have found relief in building models in-sample only for 2004, but optimizing over all chart pages. Then you don't lock onto great patterns from the past that no longer exist.

PS - We prefer a different terminology. Both neural nets and GAs curve fit. Curve fitting isn't a bad thing, because that's pretty much all we can do with history using just about any kind of technical models (unless you want to go with Bizarro models). It is OVER-fitting that is the bad thing. In the case at hand we're all fitting the great years because they made so much money.

On 11/10/2005 9:21:15 AM Dan wrote:
Mark,

I've been working on some models using the 30 trades per DOF guideline, and am beginning to see some possibilities emerge. However, I am hitting a particular snag consistently, and I wonder if you (or the Ward folks) have any insight/suggestions. It seems like the number of trades I need to validate a model demands about 5 yrs. of testing; the resulting equity curve (while profitable overall) is consistently flat toward the right edge of the chart, where I need to start trading.

For example, let's take a simple 2 indicator crossover system (I am using some add-on indicators). I optimize 2 indicators for longs, and 2 indicators for shorts. (I like for values for longs and shorts to be different b/c the market accelerates downward more quickly than upward.) This equals 4 variables, therefore the model would need 120 trades to validate. In addition, I like to use an exit indicator, which sometimes I will optimize as linked for longs/shorts. This brings the minimum no. of trades up to 150-180 depending on whether the exit variables for long/shorts are linked or not.

I find that I need to go about 5 yrs. back in order for the model to accumulate that many trades. No matter what objective I use to optimize the equity curve (max return * equity curve corr. is my favorite), the GA seems to produce results that are great in the first 3 yrs or so, but, again, mostly flat for the last year or so.

Any suggestions/ideas? Is there any way to ask the GA to steepen the curve toward the end of the model, or valid shortcuts around the 30 trades per DOF guideline?

Many thanks for your kind attention--

Dan Melton

On 10/22/2005 4:38:30 PM Mark Simpson wrote:

Hi Dan,

DOF means a lot of different things to different people, however the way I approach
it is as follows.

To me a degree of freedom is an item that can change in a model. This could be:
1. A parameter to an indicator
2. Choice of indicator
3. Choice of security

All this is pretty vague, so hopefully the following examples will clarify it:

Model Inputs: RSI(x) on 1 security where x is optimized.
Answer: 1 DOF as x is a variable parameter i.e. it can change.

Model Inputs: RSI(5) on 1 security.
Answer: 1 DOF (as you need to validate the model on something).

Model Inputs: MACD(close,12,26) on 1 security
Answer: 1 DOF (as you need to validate the model on something).

Model Inputs: MACD(close,x,y) on 1 security where x/y are optimized.
Answer: 2 DOF (x and y)

Model Inputs: MACD(RSI (z), x, y) on 1 security where z/x/y are optimized.
Answer: 3 DOF (x, y and z)

Model Inputs: MACD (RSI (z), x, y) where z/x/y are optimized, and then we try
different stocks against it to find which ones perform best.
Answer: 4 DOF (x,y,z and stock selection)

Model Inputs: Indicator(x) where x is optimized, and we try many different indicators
to find one that works on 1 security.
Answer: 2 DOF (x and Indicator selection)

Model Inputs: MACD(close,5,20) where we just guessed 5,20 as being the parameters
on 1 security.
Answer: 1 DOF (as you need to validate the model on something)

Model Inputs: MACD(close,5,20) however, we tried many different values for 5 and 20 until we found the ones that worked on 1 security.
Answer: 2 DOF (becuase you were manually changing both the 5 and 20).

So if you let the optimizer choose a value, 1 DOF gets added. If you
manually choose a value through experimentation, 1 DOF gets added.

In addition, I like to use an exit indicator, which sometimes I will optimize as linked for longs/shorts. This brings the minimum no. of trades up to 150-180 depending on whether the exit variables for longs/shorts are linked or not.

I find that I need to go about 5 yrs. back in order for the model to accumulate that many trades. No matter what objective I use to optimize the equity curve (max return * equity curve corr. is my favorite), the GA seems to produce results that are great in the first 3 yrs or so, but, again, mostly flat for the last year or so.

Any suggestions/ideas? Is there any way to ask the GA to steepen the curve toward the end of the model, or valid shortcuts around the 30 trades per DOF guideline?

Many thanks for your kind attention--

Dan Melton

Hi Dan,

DOF means a lot of different things to different people, however the way I approach
it is as follows.

To me a degree of freedom is an item that can change in a model. This could be:
1. A parameter to an indicator
2. Choice of indicator
3. Choice of security

All this is pretty vague, so hopefully the following examples will clarify it:

Model Inputs: RSI(x) on 1 security where x is optimized.
Answer: 1 DOF as x is a variable parameter i.e. it can change.

Model Inputs: RSI(5) on 1 security.
Answer: 1 DOF (as you need to validate the model on something).

Model Inputs: MACD(close,12,26) on 1 security
Answer: 1 DOF (as you need to validate the model on something).

Model Inputs: MACD(close,x,y) on 1 security where x/y are optimized.
Answer: 2 DOF (x and y)

Model Inputs: MACD(RSI (z), x, y) on 1 security where z/x/y are optimized.
Answer: 3 DOF (x, y and z)

Model Inputs: MACD (RSI (z), x, y) where z/x/y are optimized, and then we try
different stocks against it to find which ones perform best.
Answer: 4 DOF (x,y,z and stock selection)

Model Inputs: Indicator(x) where x is optimized, and we try many different indicators
to find one that works on 1 security.
Answer: 2 DOF (x and Indicator selection)

Model Inputs: MACD(close,5,20) where we just guessed 5,20 as being the parameters
on 1 security.
Answer: 1 DOF (as you need to validate the model on something)

Model Inputs: MACD(close,5,20) however, we tried many different values for 5 and 20 until we found the ones that worked on 1 security.
Answer: 2 DOF (because you were manually changing both the 5 and 20).

So if you let the optimizer choose a value, 1 DOF gets added. If you
manually choose a value through experimentation, 1 DOF gets added.

This thread is about curve fitting. I also refer you to Steve Ward's tips on preventing
over-optimization http://www.ward.net/cgi-bin/viewtip.asp?ID=105 as a guideline for
what you can do to avoid it.

So, lets start off with what a GA (Genetic Algorithm) is, to remove some of the mysticism behind the GA built into Neuroshell. Personally I believe that it's
by understanding the principles of this that it can be better used to advantage.
The GA is a very powerful tool if used correctly, if used incorrectly it can sink
you.

You've probably come across the following problem, you build your
system, keep optimizing various types of system until you find one that does well,
then you trade it in realtime, and poof, that well performing system eats you alive.
If you've done everything else correctly, i.e. tested on out samples and used walk forwards, then the chances are you've just incorrectly curve fitted without realizing it.

So what is curve fitting? If you imagine your trading system like this, you
have inputs and you have an output (trading signals). You have a black box in the middle which translates between. Essentially the output is a function
of the input. I.E. Output=f (Input1 ..Input N)

The output is the curve, i.e. it's a varying function, and the idea is that we have to
design the function so that it fits that curve.

So, lets translate this to the NST world. We use a bunch of indicators to go into
our "function", and then see how well the function works (performance). However
it doesn't do too well, so we use the optimization feature in NST (a GA) to alter
the parameters to the indicators to make the function fit the curve better.

A Genetic Algorithm (GA) is just a tool to reduce the search space. For instance
if you had 5 indicators with a total of 10 possible parameters, then to try every
possible combination would take a long time. Trying every possibility is a brute force
method and isn't practical unless your model is extremely simple.

A GA looks at the problem differently. If we wanted to find the highest peak in a range of mountains, then visiting every mountain takes too long, so a GA
uses a targetted approach. I.E. You guess a local peak to begin with. It probably
isn't the highest peak, so you guess again. Then using a chromosome/gene
model borrowed from biology, where you have survival of the fittest, you match the good parameters of the mountains and keep going. Essentially you keep going, at every generation, the fittest members survive to keep going, until you can make no more "reasonable" improvement. I.E. Your solution evolves to find the best answer
just like life on earth. What's happening is your taking spot readings over the range
and homing in on the highest mountain.

A GA has a fitness function (in this case the height of the mountain), in the case of
trading, it's your goal. The GA is a tool to help us fit the curve. A brute force method can be better than a GA, but if a GA doesn't reach the correct answer, it will likely
reach one that's close. I.E. In the trade off between brute force and a GA, GA is
really only the practical way to go, although brute force may be occasionally a little
more superior in result.

So lets try some examples of incorrectly curve fitting with a few examples.

CURVE FITTING WITH TOO LITTLE DATA:

So we toss some coins. Coins can be heads or tails and our goal is to build a perfect
coin toss predictor. We toss 3 times, and get heads each time. Therefore we
optimize our solution, and build a perfect coin tosser that always generates heads
as the answer. So what's wrong?

Well, our curve is heads/tails, but we took such a small sample (of size 3), that
we didn't see the real picture. I.E. We tried to fit a curve where we couldn't see the whole curve. In trading, this is a classic mistake that is commonly made. We genetically optimize with not enough data. Remember from before that to be
reasonably confident that we haven't incorrectly curve fitted the data, we need
30 trades per degree of freedom (DOF) for every variable in the model.

This shows up as, building a model that optimizes well, then trades poorly in real time.
If you tested with adequate data, you'd have found out that it really was poor in the
first place.

CURVE FITTING BY SELECTION: STOCK PICKING

We can also incorrectly curve fit by picking results, without even using a GA.

For instance, if you were to trade say 10 stocks randomly for a period of time,
you'd likely make money on some and lose money on others. Just like tossing
a coin would produce heads and tails.

So you have your perfect model and you want to trade, but it works on some stocks
not others, so you plug in 100 stocks to find out which ones do well and which ones
do poorly, and keep the good ones. Well you've just incorrectly curve fitted by
another means. (or another way of looking at it is rendered your out of sample to be in sample). This is because out of any population (the 100), if you pick and choose your sample (the good ones), then your sample is no longer truely representative of your population.

CURVE FITTING BY SELECTION: INDICATORS

So, instead of picking the best stocks to use in your model, you pick the best indicators, i.e. just keep plugging at it until you find indicators that work.
Again, just another form of incorrect curve fitting for the same reason as the
last.

CURVE FITTING BY SELECTION: PICKING THE BEST RESULTS

So you keep trying models until you find the best one. Again, just incorrectly curve fitting.

As you can see, this is a huge problem, there are so many ways to incorrectly
curve fit. Anywhere where you pick and choose, or try different things open you
up to curve fitting.

One solution might be to create another out of sample testing to get around the problem. But again, if you pick and choose between those out of samples, you're
opening yourself up to the same problem again.

So, incorrectly curve fitting is not 100% avoidable, but needs to be realized and
managed. Personally I follow this method to avoid it as much as possible:

1. Never try things out in a model in an untargetted approach, and
this is where these threads about design models come into the picture. Start off
with a goal, and design a model to fit that goal, don't just guess at methods or
indicators that will work, start off with solid design from the ground up.

2. Use a GA to improve good models, not to make bad models work.

3. If using a GA, use it at the end of the process, i.e. as a final improvement to an
already good model.

4. Use sufficient data to test with.

5. Always keep additional out of samples to test on. A good out of sample is
always paper trading.

6. Never pick and choose results, stocks or anything else. (At least not without being aware of it and knowing the effect).

7. Keep degrees of freedom low. I.E. The smaller the DOF, the less data you need to validate which makes everything a lot simpler to test.

USING CURVE FITTING TO ADVANTAGE:

There is another way to approach curve fitting and make it work to your advantage. At first it seems like a crazy approach, but there are good reasons why it works. That is to keep DOF small and optimize frequently.

The reason for this is because of the curve fitting. Normally we wish to fit that curve perfectly, however, any curve can be approximated by a series of small lines. This is called a Piecewise Linear Approach. Linear = Line, Piecewise means small pieces.

I.E. If you keep Degrees Of Freedom (DOF) low so that your fit can be validated in minimal time, i.e. you're creating a small line, then it can fit (approximately) the curve of your function for a small period of time. You then reoptimize frequently to get additional small segments of lines.

Re: Curve fitting, What it is, how to avoid it and how to use it to advantage

Date :10/22/2005 7:30:49 PM Poster : Maciej

Mark, Are you aware of any way to force the GA to give only integer or fractional results? I trade grains and my corn futures goin steps of 0.25 so a stop of say 200.33 is not really optimal - ideally I'd like to get a result of either 200.25 or 200.50. Or is that the inherent nature of GA prevents such solutions?

Hi Maciej,

It's possible to do, but it has to be a time series, as standard parameters can't take indicators as parameters.

If you can provide the formula and identify the parameter you're trying to achieve a trading increment with I can tell you if it's possible or not.

If it turns out to be a time series solution, I have an indicator here that will do the job.

The GA can't be made to match minimum price increments on futures, but NeuroShell really needs some sort of rounding feature where prices are concerned, as in stops. However, you can probably effect this yourself by putting rounding in the stop price. For 0.25 increments, use the Quotient indicator, dividing the price by 0.25. Then multiply by 0.25. That should round what the optimizer gives to the nearest quarter point.

So what is curve fitting? If you imagine your trading system like this, you have inputs and you have an output (trading signals). You have a black box in the middle which translates between. Essentially the output is a function of the input. I.E. Output=f (Input1..Input N)

The output is the curve, i.e. it's a varying function, and the idea is that we have to design the function so that it fits that curve.

So, lets translate this to the NST world. We use a bunch of indicators to go into our "function", and then see how well the function works (performance). However if doesn't do too well, so we use the optimization feature in NST (a GA) to alter the parameters to the indicators to make the function fit the curve better.

A Genetic Algorithm (GA) is just a tool to reduce the search space. For instance if you had 5 indicators with a total of 10 possible parameters, then to try every possible combination would take a long time. Trying every possibility is a brute force method and isn't practical unless your model is extremely simple.

A GA looks at the problem differently. If we wanted to find the highest peak in a range of mountains, then visiting every mountain takes too long, so a GA uses a targetted approach. I.E. You guess a local peak to begin with. It probably isn't the highest peak, so you guess again. Then using a chromosome/gene model borrowed from biology, where you have survival of the fittest, you match the good parameters of the mountains and keep going. Essentially you keep going, at every generation, the fittest members survive to keep going, until you can make no more "reasonable" improvement. I.E. Your solution evolves to find the best answer just like life on earth. What's happening is your taking spot readings over the range and homing in on the highest mountain.

A GA has a fitness function (in this case the height of the mountain), in the case of trading, it's your goal. The GA is a tool to help us fit the curve. A brute force method can be better than a GA, but if a GA doesn't reach the correct answer, it will likely reach one that's close. I.E. In the trade off between brute force and a GA, GA is really only the practical way to go, although brute force may be occasionally a little more superior in result.

So lets try some examples of incorrectly curve fitting with a few examples.

CURVE FITTING WITH TOO LITTLE DATA:

So we toss some coins. Coins can be heads or tails and our goal is to build a perfect coin toss predictor. We toss 3 times, and get heads each time. Therefore we optimize our solution, and build a perfect coin tosser that always generates heads as the answer. So what's wrong?

Well, our curve is heads/tails, but we took such a small sample (of size 3), that we didn't see the real picture. I.E. We tried to fit a curve where we couldn't see the whole curve. In trading, this is a classic mistake that is commonly made. We genetically optimize with not enough data. Remember from before that to be reasonably confident that we haven't incorrectly curve fitted the data, we need 30 trades per degree of freedom (DOF) for every variable in the model.

This shows up as, building a model that optimizes well, then trades poorly in real time. If you tested with adequate data, you'd have found out that it really was poor in the first place.

CURVE FITTING BY SELECTION: STOCK PICKING

We can also incorrectly curve fit by picking results, without even using a GA.

For instance, if you were to trade say 10 stocks randomly for a period of time, you'd likely make money on some and lose money on others. Just like tossing a coin would produce heads and tails.

So you have your perfect model and you want to trade, but it works on some stocks not others, so you plug in 100 stocks to find out which ones do well and which ones do poorly, and keep the good ones. Well you've just incorrectly curve fitted by another means. (or another way of looking at it is rendered your out of sample to be in sample). This is because out of any population (the 100), if you pick and choose your sample (the good ones), then your sample is no longer truely representative of your population.

CURVE FITTING BY SELECTION: INDICATORS

So, instead of picking the best stocks to use in your model, you pick the best indicators, i.e. just keep plugging at it until you find indicators that work. Again, just another form of incorrect curve fitting for the same reason as the last.

CURVE FITTING BY SELECTION: PICKING THE BEST RESULTS

So you keep trying models until you find the best one. Again, just incorrectly curve fitting.

As you can see, this is a huge problem, there are so many ways to incorrectly curve fit. Anywhere where you pick and choose, or try different things open you up to curve fitting.

One solution might be to create another out of sample testing to get around the problem. But again, if you pick and choose between those out of samples, you're opening yourself up to the same problem again.

So, incorrectly curve fitting is not 100% avoidable, but needs to be realized and managed. Personally I follow this method to avoid it as much as possible:

1. Never try things out in a model in an untargetted approach, and this is where these threads about design models come into the picture. Start off with a goal, and design a model to fit that goal, don't just guess at methods or indicators that will work, start off with solid design from the ground up.

2. Use a GA to improve good models, not to make bad models work.

3. If using a GA, use it at the end of the process, i.e. as a final improvement to an already good model.

4. Use sufficient data to test with.

5. Always keep additional out of samples to test on. A good out of sample is always paper trading.

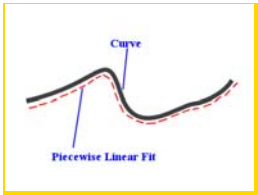
6. Never pick and choose results, stocks or anything else. (At least not without being aware of it and knowing the effect).

7. Keep degrees of freedom low. I.E. The smaller the DOF, the less data you need to validate which makes everything a lot simpler to test.

USING CURVE FITTING TO ADVANTAGE:

There is another way to approach curve fitting and make it work to your advantage. At first it seems like a crazy approach, but there are good reasons why it works. That is to keep DOF small and optimize frequently.

The reason for this is because of the curve fitting. Normally we wish to fit that curve perfectly, however, any curve can be approximated by a series of small lines. This is called a Piecewise Linear Approach. Linear = Line, Piecewise means small pieces.



I.E. If you keep Degrees Of Freedom (DOF) low so that your fit can be validated in minimal time, i.e. you're creating a small line, then it can fit (approximately) the curve of your function for a small period of time. You then reoptimize frequently to get additional small segments of lines.

Suggestions for using Fuzzy Sets add-on

Date :8/31/2005 4:59:20 PM Poster : MFK

I'm having mixed results using the Fuzzy Sets indicators, and I think the problem is lack of understanding of how to implement the sets in a trading strategy. (The fuzzy logic theory behind them makes so much sense that I'm determined to learn how to use fuzzy sets wisely. If you own this add-on and haven't read Bart Kosko's Fuzzy Thinking, do so immediately.)

First question deals with using the conditional fuzzy sets with the GA optimizer. Let's saying I'm using RSI(10) to create a buy signal. For the Sets parameter, I specify a range of 3 to 7. Here's where I get a little confused. What range do I specify for the Set parameter? According to the Help file, I probably want to start at 0 to determine if indeed the indicator contributes nothing. Do I then set the maximum of the parameter range to 7, the maximum number of sets I specified for the optimization? Or do I use the default setting, 0 to 10? I've done the latter, and I wind up with puzzling results when I look at the final trading rules; for example: 3,RSI(10),9. If I'm reading that result correctly, it means the optimizer has divided the RSI indicator into 3 sets, then is using the ninth set to produce the result. How can that be?

Second question deals with the range of data used to create the Sets parameter. The Help files says the minimum and maximum of the range is based on the values observed in the chart. Does that mean all data loaded, including data up to the most recent chart date? Or is the data limited to that used during optimization but not that used to evaluate out of sample results?

Third question seeks some observations and suggestions from experienced users. What could be causing me to get good to very good signals for buys, but few if any signals for sells? In most of my testing, I'm either in the market in a buy-and-hold position or I'm eventually stopped out by a trailing % stop. One thought I've had is I'm just not training the fuzzy sets long enough? Are these time-intensive, similar to Neural Indicators? Or is my confusion with Sets and Set causing my problem?

It would be great if we could establish a forum focused almost exclusively on fuzzy logic and fuzzy sets. (Read Kosko's book to learn why the word "almost" is required in that sentence.)

Noob Question: Difficulty with ATR DLL

Date :9/2/2005 4:30:50 PM Poster : NStrader

I'm trying to implement Average True Range as a DLL. My problem is that the code below compiles (I know its crude, but once I know it's working it could be 'boilerplated'), but NS has a hissy fit and crashes after I've registered and tried to use it. I don't think the problem is with the code but...

```
#define DLLF _declspec(dllexport)
#include <stdlib.h>

DLLF void ATR(double *high, double *low, double *close, long period, double coeff, double *outp, long numbars)
{
// Variables.....
const double noCalc = 3.4e38; // NS's standard for 'no output'.
double pastClose = 0.0; // Yesterdays Close.
double *trueRange = new double[]; // Contains True Range value.
double tr = 0.0; // stores 3 cond.'s for TR.

// Test for correct values.....
if( period == 0) // Crude error detection. Will be replaced by
abort(); // ...AfxMessageBox when I have proved that this
if( coeff == 0.0) // ...works.
abort();
if( numbars == 0)
abort();

// Set initial conditions.....
pastClose = *close; // Needed for one of the three TR numbers.

// Calc True Range and store in trueRange[].....
for (long i=0; i<numbars; i++)
{
if(i==0)
trueRange[i] = (high[i] - low[i]); // Start TR condition.
else
{
if((high[i]-pastClose) < (high[i] - low[i])) // Calc.'s TR.
tr = (high[i] - low[i]);
else
tr = (high[i]-pastClose);
if( tr < (low[i]))
tr = low[i];
}

trueRange[i] = tr; // Store TR reault.
pastClose = close[i]; // Update - look to past Close.
}

// Calc Average True Range.....
for(long l = 0; l < (period - 1); l++) // Tells NS noCalc in this range.
{
outp[l] = noCalc;
}

for(long j = 0; j < (numbars - period); j++) // Main outer loop.
{
double sum = 0.0;
for(long k = j; k < (j + period); k++) // Inner Mov Avg loop.
{
sum = sum + trueRange[k]; // Sum all TR in period.
}
outp[j+period] = ((sum/period) * coeff) + close[j+period]; // ATR calc.
}

// Tidying up loose ends.....
delete [] trueRange; // Free memory used.
}
```

I have implemented the example .dll's without problem - so I'm obviously missing something. Please, can someone help?

Re: Noob Question: Difficulty with ATR DLL

Date :9/2/2005 6:08:48 PM Poster : Mark Simpson

Try changing the line:

double *trueRange=new double[];

to:

double *trueRange=new double[numbars];

as you are accessing a pointer which doesn't point to any data.

I haven't gone through the rest of the logic in the code, but that should solve
your problem with running it. Windows doesn't handle pointer errors too elegantly.

Ibasic DLL compiler now only $49.99

Date :9/8/2005 4:27:14 PM Poster : Ward.net Webmaster

It looks like the price of Ibasic Pro is now only $49.99 on www.pyxia.com. If you want to write your own indicators for NeuroShell in BASIC, this is a great deal. There is an example on this site of an Ibasic indicator.

Re: Ibasic DLL compiler now only $49.99

Gentlemen,

I programmed in PL1 in college 35 years ago (please stop laughing) and did no further programming until I picked up TradeStation 2000i in 1999.

I am less concerned with how much the BASIC product costs and much more concerned with
* How easy is it to learn and use relative to Power Basic?
* Which of the 2 compilers do you plan to use for your future examples?
* Is one product more general purpose than the other?

In short do you have a recommendation?

Thanks.

Mike Begley

Date :9/26/2005 8:42:21 AM Poster : Steve Ward

I'm the only one here old enough to remember PL1. You learned PL1 and you're worried about how easy IBASIC is to learn? If you programmed in PL1 you are smart enough to program in anything!

We haven't done any side by side tests with Power Basic, and in terms of future examples, we'll probably let our folks use whatever they want - whatever they are already used to is what they will probably use. I personally like IBASIC better than PB only because I think the method of referring to arrays passed by NeuroShell is more natural and more consistent with other array processing. Therefore I'd call it easier to use, because array passing is what intimidates people the most about programming for NeuroShell. IBASIC PRO has a 15 day free trial - download it and try it.

As a licensee who updates both compilers on a regular basis, I would say that both IBasic and Power Basic will continue to be supported in the future, based on the power of the user forums, and the spirit of the authors.

IBasic is certainly the less expensive, and it gets the job done well. (also support of assembler via NASM assembler using inline code in the Ibasic code.)
So it makes sense for new adopters of custom programming of dlls for NST that they would benefit economically by adopting Ibasic. Of course, if you are experienced in Power Basic, and have a license, why change? On some benchmarks, using code in the Ibasic forums, your Ibasic can run twice as fast as Power Basic. Then again, other code run in Power Basic could be faster than the same as in IBasic. If you are fussy, get both.

I certainly hope Ward Systems supports both, they deserve the support.

Date :10/1/2005 9:33:12 PM Poster : Michael J Begley

Thanks guys for all of the comments. I am cracking open the Ibasic help files this afternoon.

I used PL1 when I took some breadth type courses during MSEE studies. After an intro programming practices class, where I wrote an assembler, I used PL1 for assignments and projects in several mathematical pattern recognition classses. I found it VERY difficult to debug especially when the human interface with the mainframe was punched cards. I could not tell you what the roots of PL1 were. I remember looking at the source code for a matrix inversion subroutine in the Scientific Subroutine Package. What a mess! There were GOTO branches going off in all directions -- and everything else the programming practices class preached against.

Well, fortunately life is easier today!

Mike Begley

classification nets

Date :9/17/2005 9:23:36 PM Poster : frank

Can the Turboprop 2 net be used as a classification net if given enough hidden layers or is it set up to be strictly a dynamic time series net?

Re: classification nets

Date :9/19/2005 2:12:03 PM Poster : Jennifer

I've done it before and here's how I remember doing it. Just make an indicator with lead of momentum that is 1 if the market is going up, and -1 if going down. Then use that as an output in a prediction of 0 days ahead. When the prediction is gt 0, you buy, and vice versa. I studied a different kind of ANN in school, but I don't think hidden layers matter at all.

On 9/17/2005 9:23:36 PM frank wrote:

How to speed up the startegy optimization

Date :9/20/2005 4:22:20 AM Poster : vvv999vvv

When I try to backtest a trading strategy (cross over and cross under strategy) in Forex on 15 minutes chart (started from 4/5/05)for four tickers, it took me more than two days to finished, any suggestion to speed up the optimization. TIA

Re: How to speed up the startegy optimization

Date :9/20/2005 12:25:59 PM Poster : Mark Simpson

Try these in order:

1. Change UNLOADCUSTOMDLLS from True to False in \windows\nstrader.ini
This makes sure that the dlls aren't unloaded on each interation of the optimization.

2. Constrain the optimization by setting ranges of values for each of the parameters
for each indicator.

3. Examine the model. How many indicators? How many parameters? Try to
reduce it.

4. Code it in a programming language.

5. Get a faster machine.

Mark,

Thank you

1/ my default setting is false

2/ I have retrained the setting range

3/ it is 3 to four indicators, except a "strategy" from the default indicator, such as maxium value since order is filled

4/ all of them are indicators by Neuroshell, turning points, neural indicator and cybernatics

5/ It is a Xeon pc with 2G ram

THank you for your reply.

Plenty of aricles exists on this site.
I've found that my better strategies are already good with very little optimization.
Try to limit the ranges of your variables - It can be a bit fastidious to set up the vairables and their ranges but it pays.
Work progressively - entry+exit+stop for both long and short = max.
If you work progressively, say entries only then add exits and then stops you'll quickly get a feel for the cost of each component of a strategy. There are further articles her on why for instance stops can add to the optimization process a lot of time.

Hi, Maciej

I agree, I just try to built a simple system with a few indicators

For instant, I try to smooth the data before I applied the strategy in order to reduced the whipsaw on hour chart (I think 4 hour chart will do better, unfortunately, Neuralshell has no 4 hour interval chart, it is one of its drawback),
Then I applied one cybernatic cross over and below strategies, it takes ages to finish any strategy.

I agree simple is good, but sometimes, it is hard to acheive. Like recently, I found a startegy of over 5000% profit (1 % margin on forex), but unfortunately, in real trade on range market, it is keep on losing as the lag is more than 8 hours , so when the signal is given, it will turn to other side very soon, any suggestions? TIA

I haven't tried using 4 hourly charts but there is a MT (Mulitple Timeframes) set of indicators that were donated by a fellow users available on this site. You may want to experiment with them.
I smooth data a lot. I'm particularly fond of the Jurik JMA even though I find Jurik's software keys a real pain whenever I upgrade a bios - Jurik want's the name and copy of the bios like he doesn't believe you. Otherwise the software is fine. He has some other tools to smooth data but they prbably don't lend themselves well to real-time (JMA is ok). I find that in back testing futures I can hit the 100+% returns quite easiliy but its a lot more difficult to get that in real life + you need guts to survive the drawdowns sometimes.

Hi, Maciej

Thank you for reply.

THe reason I think of four hour chart is we shall have less whipsaws compare with the one hour chart, and day chart is even better on this aspect, I tried a backtest with day chart on 4 main forex pairs and returns all winner without loser by applying Cybernetic Laguerre filter, the drawback of Laguerre filter is for very long run. On the other hand, Cybernetic 2-pole and 3-pole super smoother are good, but lag always cause some troubles, as times goes on, it is getting better results.

For forex trading, the usual margin is 1%, it can return over 2000% on Lagurerre filter and 5000% on 2-pole or 3-pole filter (max over 9000% on Chf in hourly chart), personally, I recommand it is worthwhile to read on the book.

Good trade

Suggestion for automating Neuroshell

Date :9/27/2005 9:38:05 PM Poster : Sunny

I have been thinking about how nice it would be able to go on vacation for the summer and to be able to leave Neuroshell trading on its own for me.

However, after thinking about it and talking with other users of the program, I have concluded that this would be a perfect way of losing money.

More experienced traders and users of Neuroshell have told me that this would not be possible since it would be dangerous to leave the program trading without supervision. I have thought about it, and I have come up with the same conclusion.

Suppose I had the perfect trading strategy for trading something with Neuroshell. This trading strategy would be working on intraday data. Most users (including Steve Ward) would probably say that after a few days of trading, I would require to retrain all my predictions including my trading strategy.

I don't know if they say this out of experience, or if they say this from watching a degradation of certain parameters; however, this appears to me almost a unanimous conclusion.

Now, in order to avoid this conclusion the program would have to detect these degradation of parameters itself, and it would have to retrain both its predictions and trading strategy by itself.

Alas, this currently is not possible to do since the program is unable to retrain all of its predictions and trading strategy(s) on its own, but I thought of placing this note on the forum since the good people of Ward are currently working on an upgrade to the program.

Perhaps on the next upgrade they will figure out a way for the program to test which indicators work best in predicting something. Perhaps it will even learn how to decide which inputs work best for predicting something that the program chooses on its own. Now that would be real artificial intelligence working at its best...

Regards,

Sunny

I think maybe you asking for more of our programing friends than may be realistic, Sunny, but it sure would be nice!

Here's a request from me. I'd be curious to know if anyone else would think that such a feature would be usefull. Here goes:

I'd like to be able to "tag" a chart as "active" (or some such designation). Then have a quick key command that would have all such "tagged" charts update (as if I had opened each one idividually) and then output any new trade signals to a text file (that had the same name as the chart). Such a feature would help me go a long way towards automating the whole trading process and remove human error.

Manny,

Your idea runs pretty close to what I had in mind with the exception of the text file. It sounds to me like you are running some type of batch process for different securities.

You are essentially trying to automate the training process (for which I am coming to the conclusion that all neural network software companies should make a full disclosure to new customers -- CUSTOMER BEWARE, THE RETRAINING OF NETS MIGHT REDUCE YOUR FAMILY AND FRIEND LIFE BY A CONSIDERABLE AMOUNT) which at this stage of software development appears to be back in the dark ages since the user is actually a slave for the program in order to keep it actualized.

I have been researching some Macro software programs that do part of this; I have essentially found that you could retrain some predictions; however, once in a while I get a message, before completing the retraining process, asking me if I want to retrain the Trading Strategy (essentially popping at non predictable places in the retraining process). My Trading Strategies, as you might imagine, depend on different predictions.

This makes it difficult for me to implement a Macro strategy to retrain the nets.

I still think the ideal situation would be to have Neuroshell ask you if you want to have the nets retrained and how often.

Regards,

Sunny

>I still think the ideal situation would be to have Neuroshell ask you if you want to have the nets retrained and how often.

That is why we built Adaptive TurboProp 2 and Adaptive Net Indicators. AT2 retrains on the interval you specify, and ANI are always retraining. Even with the Prediction Wizard, I'm a little confused. All you have to do is hit the Retrain button and off it goes. If you have 50 stocks in a chart they all retrain. If you have a lot of charts, yes, they will have to be all loaded, but in release 5.0, we have a "workspace" that contains x charts - you just have to load a workspace and all the charts come up.

Re: Suggestion for automating Neuroshell

Date :10/5/2005 2:35:57 AM Poster : Sunny

Steve,

My problem as far as retraining is concerned has to do with the fact that I am working with an unusually large number of predictions, and, moreover, these predictions serve as input to other predictions, and these final predictions serve as inputs to different trading strategies.

If I had a single prediction, then hitting the retrain button would be no big deal. The problem is that after I hit the retrain button on the first prediction, I have to pay attention when it completes its predictions, and then I have to open up the next prediction and repeat the process until I finish. In the meantime, I get pop up windows (at different stages of the retraining process) asking me if I would like to retrain the prediction that depends on the previous predictions as inputs, or if I would like to retrain the trading strategy.

The only reason I go through this masochistic process is due to the fact that the relationships built hold well over time. I have tried less complicated relationships with lesser number of predictions; however, the results breakdown over time.

The whole process can take several hours every weekend. I did buy sometime ago from Marge one of the indicators that you mentioned; however, I got confused as to how to enter all of the many predictions to be retrained into it, and I never actually got to use it.

My preferred scenario would be one where the program actually retrains all of these predictions on its own. This would free up a huge chunk of my time every weekend, and I could use this extra time to sleep, to relax, or to be with my family.

Best regards,

Sunny

All charts update automatically when you bring them up if new data is there - no tagging is necessary. In release 5.0 there is a feature we call the Trade Pump - a programmable interface that gets trades when they occur into your program. You can tag which charts send out trades. You can save trades or send them to a broker. At least one brokerage will be included. We are currently working on an example for Trade Pump that emails the trades to an email list. Maybe those things will help you.

t tests and neural net based trades

Date :9/29/2005 12:47:20 AM Poster : MannyL

I'm working with some software that performs a Student's t test on an input series of trades so that a confidence level of profitability can be determined. (Market System Analyzer www.adaptrade.com It's vey good.) In order to be meaningful it is necessary to know the number of conditions in the trading system that if changed would change the result. The length of the moving averages in an moving average crossover system would consititute such variables. The number of inputs and the number of neurons in a neural net would certainly count as such variables as well. My question is should I be acounting for the number of weights in the net? In other words instead of adding the number of inputs and the number of neurons should I be multiplying them? Anyone have any insights here? Thanks in advance.

Re: t tests and neural net based trades

Date :9/29/2005 1:14:05 PM Poster : Steve Ward

The t test or student t test can indeed be used to calculate a confidence range of a population mean from a sample mean (in this case the sample consists of trades from a fixed system). It is a simple calculation any stat book has, so you don't really need software. Degrees of freedom for the t test in my stat book is defined as the number of observations minus the number of parameters to be estimated beforehand (e.g, if you are estimating the mean, then the number of parameters is one). It doesn't have anything to do with the number of parameters that created the model that created the population. (We aren't talking about the same degrees of freedom used to estimate standard error of a regression!) Therefore, and especially since weights are fixed in both the sample and the population, I don't consider it valid to use neurons, weights, or even inputs to the net as "parameters" to be substracted from the population size. I strongly question even defining parameters for the t test as rules or conditions in the trading strategy. However, if you want to go along with that, then our neural nets have either 2 or 4 threshold rules, depending on if you allow both longs and shorts, or reversals:

net prediction > long entry threshold
net prediction < long exit threshold
net prediction < short entry threshold
net prediction > short exit threshold

Thanks for the feedback, Steve. That's what I needed to know.

On 9/29/2005 1:14:05 PM Steve Ward wrote:
The t test or student t test can indeed be used to calculate a confidence range of a population mean from a sample mean (in this case the sample consists of trades from a fixed system). It is a simple calculation any stat book has, so you don't really need software. Degrees of freedom for the t test in my stat book is defined as the number of observations minus the number of parameters to be estimated beforehand (e.g, if you are estimating the mean, then the number of parameters is one). It doesn't have anything to do with the number of parameters that created the model that created the population. (We aren't talking about the same degrees of freedom used to estimate standard error of a regression!) Therefore, and especially since weights are fixed in both the sample and the population, I don't consider it valid to use neurons, weights, or even inputs to the net as "parameters" to be substracted from the population size. I strongly question even defining parameters for the t test as rules or conditions in the trading strategy. However, if you want to go along with that, then our neural nets have either 2 or 4 threshold rules, depending on if you allow both longs and shorts, or reversals:

net prediction > long entry threshold
net prediction < long exit threshold
net prediction < short entry threshold
net prediction > short exit threshold

be careful with statistics. a big issue in using tests like this is making sure you sample from the right population. trades made in backtesting aren't of the same population as trades made later. use your real trades done after you have built your system to sample real trades into the future, then the t test might be more accurate. the more trades sampled the better.

Student t may not be an appropriate test because the distribution of trades may not be normal.

In any event, the number of variables can be determined by opening the Trading Rules tab under Detailed Analysis for the strategy. Count every number for all conditions that wasn't linked for optimization (i.e., count each link parameter only once). The total is number of parameters.

Greg,

I have been working on the side with Excel. It allows me to determine what percentage of observations fall under a normal distribution, a gaussian distribution, a gamma distribution, etc. I get a number between 0 and 1 for each test that I make to determine the type of probability density that my data is most likely to match.

Once I have an answer, I can continue with other questions that are appropriate to the type of probability density at hand.

I suppose if I had the same in NS, it would be something like this:

If probability density matches normal distribution by 0.8 or more, then do the following, else, if the probability density matches a gamma distribution by 0.8 or more, then do the following.

I have been wondering if it is possible to do these types of questions in NS, but I am not sure if we have different probability densities available.

I think it would be useful if someone would make a complete statistical add-on with different statistical tests to try in NS. I wish I could do this myself; however, my programming abilities are quite limited.

Regards,

Sunny

suggestion of include GMT on next revision
Date :10/1/2005 4:24:12 AM Poster : vvv999vvv

In trading forex, GMT time is inportant for day, week and monthy charts as you got one day less than using the EST, I remember it is the function included in the TradeStation, would like to hear your comments

Delay problem
Date :10/2/2005 6:19:04 AM Poster : vvv999vvv

I have use the cybernatic indicators on forex hourly chart, it gives very good results on trend, but serious delay on range, the trading strategy as follows:

Optimise Adaptive RVI trigger (3 pole super smoother) cross above / below Adaptive RVI (3 pole super smoother)

Any suggestions on improving the time delay of about 8 bars .. TIA

Strategy with no loser
Date :10/3/2005 6:11:38 AM Poster : vvv999vvv

For those cybernatic users,

The following startegy returns no loser, all winners, thought the return is not that big (all over 2000% for 1% margin), it applies to four main foreign currency, EUR, CHF, Jpy and GBP

Optimize Itrend trigger (Laguere filter (high+low)/2) cross above / below Itrend (Laguere filter (high+low)/2)

Re: Strategy with no loser
Date :10/3/2005 3:42:27 PM Poster : Maciej

Do you have a NSDT type formula for a Laguerre filter?

Hi, Maciej

There is a add-on from NST, Cybernetics

Also, you can found from his book of Cybernetic analysis for stocks and futures by John Ehler, imho, read his book before buy the add-ons, there is easy language and EFS code over there

vvv,

With which time frames are you using this indicator, for instance, daily, hourly, etc.?

In Laguere filter (high+low)/2) are you actually changing the PriceIn of High and low for divide(add(high, low),2)?

How many days ahead are you predicting?

What are you predicting, for instance, %change in the open?

Regards,

Sunny

Hi, Sunny

It is base on day chart,

Yes, it is average of high and low, or use NST default PriveIn = Price

Use default NST setting, it is about less than 2 years

IT is utimimunm in return

Good luck, good trade

vvv,

I tried your idea with Euro on daily charts.

For input I entered the cross above from the crossover category, for instance, (Laguere filter (PriveIn) cross (PriveIn).

I placed 3 walkforwards of 6 months and 3 optimals of 6 months.
I left the % change in the open and the 10 days to predict as they were before.
I changed in training 5 years max and 4 years minim.
I chose Max winners - losers

However, I don't have any good results with this.

Is there anything else that I should change?

TIA

Hi vvv,

I entered your formula into the trading strategy, and I did not quite obtain the number of losers that you suggested. This leads me to think that perhaps I missed something when I entered the formula; however, it appears to look like your formula. In fact, I tried it both with average(high,low) and pricein(high,low).

On the other hand, the number of losers is relatively low compared to the number of winners (I have included my trading strategy stats at the end of my post).

I tried a couple of things to make this a little more realistic.

I changed in the trading strategy the default buy a fixed number of lots for buy as many lots as possible with current account balance.

I also changed the optimization to optimize up until 6 months from now.
Therefore, there is paper trading for 6 months.

As you will be able to see, the results were not that fantastic by doing this; however, this is a good test of a model since you apply unseen data to the optimized model.

I suppose that the optimization parameters are changing through the whole price curve, and fixed parameters do not appear to be "transportable" to an untested time period.

Perhaps you or one of our more knowlegable users in the forum can address this issue.

Your model is overall better than most; however, I think you could do better by including some content into the model rather than aiming for optimized parameters, but perhaps I am assuming incorrectly that you are not including content, and you are in fact using it together with a complex relational model.

Regards,

Sunny

All the conditions are default.

On 10/10/2005 7:11:11 PM Sunny wrote:
Hi vvv,

I entered your formula into the trading strategy, and I did not quite obtain the number of losers that you suggested. This leads me to think that perhaps I missed something when I entered the formula; however, it appears to look like your formula. In fact, I tried it both with average (high,low) and pricein(high,low).

On the other hand, the number of losers is relatively low compared to the number of winners (I have included my trading strategy stats at the end of my post).

I tried a couple of things to make this a little more realistic.

I changed in the trading strategy the default buy a fixed number of lots for buy as many lots as possible with current account balance.

I also changed the optimization to optimize up until 6 months from now.
Therefore, there is paper trading for 6 months.

As you will be able to see, the results were not that fantastic by doing this; however, this is a good test of a model since you apply unseen data to the optimized model.

I suppose that the optimization parameters are changing through the whole price curve, and fixed parameters do not appear to be "transportable" to an untested time period.

Perhaps you or one of our more knowlegable users in the forum can address this issue.

Your model is overall better than most; however, I think you could do better by including some content into the model rather than aiming for optimized parameters, but perhaps I am assuming incorrectly that you are not including content, and you are in fact using it together with a complex relational model.

Regards,

Sunny

On 10/8/2005 11:28:06 PM Sunny wrote:
vvv,

I tried your idea with Euro on daily charts.

For input I entered the cross above from the crossover category, for instance, (Laguere filter (PriveIn) cross (PriveIn).

I placed 3 walkforwards of 6 months and 3 optimals of 6 months.
I left the % change in the open and the 10 days to predict as they were before.
I changed in training 5 years max and 4 years minim.
I chose Max winners - losers

However, I don't have any good results with this.

Is there anything else that I should change?

TIA

Regards,

Sunny

Date :10/12/2005 1:19:30 PM Poster : Sunny

Hi vvv,

Thank you for your reply.

I will try it later with a shorter time frame as you suggested.

Unfortunately, this week I am a little behind things so I will try to do this in the near future.

I agree with Jenny about the StochRsi, I have also gotten decent results with it in the past. In addition, I have done some experiments with the turning points indicator, but as some of the more experienced users have pointed out lag and content are issues to consider when building a useful model.

Some of my main goals for a good model:
1- It should work with different instruments.
2- It should pass the test of time (be useful regardless of market conditions and time).

Regards,

Sunny

Hi, Sunny

To my point of view, this startegy is only suitable for long term player.

If you are free, try the cross over strategies of Adaptive RVI, this give much better results, winner to loser ratio is more than 2:1

Good luck

Hi vvv,

Sorry for the delay, but I just got a moment to try your idea, and you were right.

I tried your strategy, and it gives no losers.

I have modified your idea slightly (see below).

Try it on 15-min intraday.

(last 3 or 4 months).

Produces 8 winners and no losers.

I also attempted your Adaptive RVI strategy; however, I was unsure on how to apply it.

Thanks for the idea.

Regards,

Sunny

Hi, Sunny

Nice to hear that you are success on the strategy.

I did try your idea before, but not on 15 min chart, Laguerrie filter, to my point of view, it is a long term filter, it smooth out most of the whipsaws, that is why you got so little trade on 15 min chart, read the book again, you will discover more interesting things, Ehler is so bright that that he wrote the book for many levels, and you can try the net lead as well.

Use the similar idea on Adaptive RVI, hope you will find some more profitable startegies, what is the profit and lose ratio and annual return on your startegy?

Good trade

Victor

Hi vvv,

Thank you for your reply.

I will try it later with a shorter time frame as you suggested.

Unfortunately, this week I am a little behind things so I will try to do this in the near future.

I agree with Jenny about the StochRsi, I have also gotten decent results with it in the past. In addition, I have done some experiments with the turning points indicator, but as some of the more experienced users have pointed out lag and content are issues to consider when building a useful model.

Some of my main goals for a good model:
1- It should work with different instruments.
2- It should pass the test of time (be useful regardless of market conditions and time).

Regards,

Sunny

Hi, Sunny,

I think I got the answer for , your question, shorten your time duration, as so long time duration make the NN too many compromise.

Re: Strategy with no loser

Date :10/10/2005 8:35:51 AM Poster : Jennifer

Thanks. I had a similar success, a few losers, but overall very good. I also found the stochastic rsi to be excellent as a neural net input.

For those cybernatic users,

The following startegy returns no loser, all winners, thought the return is not that big (all over 2000% for 1% margin), it applies to four main foreign currency, EUR, CHF, Jpy and GBP

Optimize ltrend trigger (Laguere filter (high+low)/2) cross above / below ltrend (Laguere filter (high+low)/2)

Re: Strategy with no loser

Date :10/10/2005 3:55:40 PM Poster : vvv999vvv

Hi, Jennifer

According to my many backtesting, I found only way you can make a big gain is not imposing any exit and trailing stop conditions, and let the trained strategy run for certain period before use it on trade in order to solve the lag problems.

Now I can easily make startegy of over 5000% gain but with lag, this will make you loss a lot in the range trade. At the meantime I am only backtesting the Cybernetic indicators, it is hard for me to found a way incorporating the turning point indicators and neural indicators and make such a gain like cybernetic on its own.

It is amazing to note that one of the forum who applied the uncertainty principle on price, if so, we should consider the duality as wil, it it a wave as well as trend.

Good luck

Survey - How many of you are successful traders?

Date :10/5/2005 10:59:46 PM Poster : Alan Rhodes

I am just curious as to how many people in this forum are highly successful traders. I will define highly successful as grossing 50% profit per year every year over a five year period. This would exclude those who get a hot streak.

Or give me your thougts as to what makes up a highly successful trader? To me, highly successful requires two things, first a high profit margin and two sustaining it over an extended period of time. This would exclude those who get a hot streak. Also a good trader should have enough diversity so that they cannot claim a drawdown in a single market as an excuse to say why they did poorly one year (obviously, I'll make exceptions for four 100% plus years and a -20% year).

I do not expect anybody to give away any trade secrets; I am just looking for inspiration.

Re: Survey - How many of you are successful traders?

Date :10/6/2005 8:53:44 AM Poster : Steve Ward

It is clear to me why you don't think you are highly successful. It's your definition. Anybody who does that well isn't wasting time on this forum, they're enjoying their yacht! Come on, this isn't the 90's. If you don't have realistic expectations, you're going to be throwing away a lot good models and pulling your hair out for nothing. Take a look at hedge fund returns lately, and they (arguably) have the best traders in the business.

It looks to me as if you're confounding NSDT with trading. To me this is a tool to help me trade; it can help a lot but short of having a fully automated trading system NSDT is primarily going to give, I hope, reasonable entry, perhaps exit signals. When I reach your 50% goals then I'll be doing what Steve suggests, until then I'll make do with more modest progress and continue to try to control my emotions better when trading.

These are the assumptions behind all my work, and I would like your opinion if you think my assumptions are wrong.
1. It is possible to develop a trading system that is somewhat randomly successful at 70% of trades, year after year after year (allowing reoptimization of course, but a predetermined rate, not when it seems to stop working.). Though I am studying futures, let's use as an example a stock system. IF such a system was 100% accurate in 2003, 70% accurate in 2004, and 40% accurate in 2005, it would not impress me. Even though such a system is 70% successful, results are not random.
2. Such a system would have over two time's gross earnings to gross losses (actually I would be ecstatic with a system that was this successful in 10 out of ten futures markets, even with only a 40% success rate.)
3. Such as system, given enough starting capitol through proper money management in a highly leveraged market, would yield 50% per year. I realize there are far more variables in money management, and I would face large draw downs, but I am just asking about gross concepts.

I look forward to your response.

Each person has to set their own goal, but if those goals aren't realistic, you are going to be throwing away good models. I suggest you set your goals according to what you could make other ways, e.g., investing or emotional trading without analytic models. In 2005 everybody including the so called experts have made less money than they did in highly trending markets or more volatile markets.

I'll just tell you what I look for, and you can take it for what it is worth to your specific circumstance. I like a smoothly rising equity curve with no BIG dips or spikes. It is nice if it made money since 2000, but the biggest test is how did it do in the past year. Almost all of my models made more money sometime during 2000-2004 even out of sample than they have in 2005, so I don't worry that there was a drop in 2005, as long as the model gets a decent return in 2005. I look for a return >20% in 2005 uncompounded.

I don't insist that the model work on every stock because I think that is unrealistic. In fact, I've lately been concentrating on DIA, SPY, and QQQQ, usually trading the emini equivalents. I like those because they are impervious to news affecting one stock or even one sector (usually). I don't even insist that a model make money on all three.

A lot. Any time you optimize you take a big chance that the optimizer will do well on the past in spite of weak rules or net inputs. Also the market is constantly changing anyway. Neural nets by themselves aren't bad if you do the right things: keep inputs and hidden neurons low, use as much training data as you can without getting ancient history in, use training data that is evenly bull and bear. When you add optimization either to nets or trading strategies, you have to be even more careful: don't optimize forever (remember the optimizer has rather arbitrary stopping criteria), don't have too many variables that are being optimized (you can limit variables from being optimized), optimize over plenty of past history (until it becomes ancient). Other things you can do include linking parameters in buy/sell rules, optimizing over several chart pages at once, using the Neural Indicators add-on (which are pretty hard to overfit even with optimization) instead of the Prediction Wizard.

Of course, if all of your rules and inputs were great (leading the market), then overfitting wouldn't exist. But given the billions of variables driving markets, that is impossible.

Pat on the back

Date :10/21/2005 2:31:42 PM Poster : Sunny

I had a conversation with Steve a couple of weeks ago, and I got the impression from my conversation with him that some of my posts in this forum were creating the impression that I thought that NeuroShell was a bad program.

I would like to readdress these issues in this post.

First of all, I think that Steve, Mike, Marge, Chris, and other members of Ward Systems are great. Whenever I have had an issue with the use of the program, they have been helpful and understanding of my problems, and they have made themselves available in addressing these issues.

Second, I like Neuroshell. I have invested several thousands of hours in learning how to use it correctly. It is not an easy program to master, and it requires patience and work. If I did not believe in the program, I would not even bother in posting in this forum, and I would have already done an emotional and accounting write off for this investment in term of money, time, and effort.

On the other hand, I don't detract from my suggestions in improving the program.
I want to concentrate in trading not in retraining the nets or in doing things that computers and programs should do by themselves. My suggestions are meant to generate discussion and insight from my personal experience.

I was one of the first to suggest, for instance, the use of several parallel processors and 64-bit addressing for Neuroshell, and when these features will be available, they will decrease the amount of retraining, they will increase the amount of memory available to Neuroshell, and they will decrease the time frames available for trading (tick frames anyone).

So to summarize, the good people of Ward Systems deserve a pat on the back for their pioneering effort, creativity, persistence, and humanity, and please don't confuse my posts with negativity. As I mentioned before, they are meant with the best of intentions, and if I stepped on someone's toes, then please accept a humble apology. '-'

Sunny,

The request for multiple processors, either on the same machine or machines coupled together, has been around for a couple of years least. If my memory serves me right the orignal Neuroshell had at one time a possibility of running with a special DSP board so the concept of using more than one processor for the cpu intensive tasks is not new and certainly understood by Ward Systems. Hopefully there'll be a day when such a capability will exist.

That capability does exist somewhere in release 5.0, as I am sure I have stated before both on this forum and in newsletters.. It is true that rel 5.0 has been a long time coming, but given current sales levels we can only employ so many people doing technical work on this program. If you really want to help, help us increase our sales level so we can employ more programmers. Do that by suggesting on forums etc. that they purchase our software. I have to say it is somewhat rare that we get a purchaser who says "I was recommended by one of your users." I would like to see that change.

Steve,

In my personal opinion, this is a good program for quality users, but it is not that easy to learn and understand for most of the users.
Take me as an example, I brought 3 add-ons, in order to understand stand how to use the cybernetics, I need to read the book again and again before I can establish a trade system. I can never apply the turning point successfully on trading system, and worst is the neuro indicator, it make me completely lost on what I am doing and it is too lengthy to do the optimzation on strategy (4 days or more) on my pc with Xeon and 2G ram, or 2 days to re-train my trading startegy with less than 5 indicators on 3 months 60 min chart and 3 weeks on 15 min chart,

I admit that I there are many indicators included in the program, I wonder how many of them can understand and use by your customers, I think this is one the reasons why the sales are limited.

May I suggest that put this forum into an open forum, so other quality users can learn what neuroshell can do and make them an alternative choice.

I was one of the first to suggest, for instance, the use of several parallel processors and 64-bit addressing for Neuroshell, and when these features will be available, they will decrease the amount of retraining, they will increase the amount of memory available to Neuroshell, and they will decrease the time frames available for trading (tick frames anyone).

So to summarize, the good people of Ward Systems deserve a pat on the back for their pioneering effort, creativity, persistence, and humanity, and please don't confuse my posts with negativity. As I mentioned before, they are meant with the best of intentions, and if I stepped on someone's toes, then please accept a humble apology. '-'

Maciej,

Mind to tell more on the DSP board and machines couple together in order to improve the performance, if I run two optimization at the same time, it occupies me 100% cpu usage. Also, what you think about the 2 core processors? TIA

On 10/22/2005 7:23:28 PM Maciej wrote:
Sunny,

The request for multiple processors, either on the same machine or machines coupled together, has been around for a couple of years least. If my memory serves me right the orignal Neuroshell had at one time a possibility of running with a special DSP board so the concept of using more than one processor for the cpu intensive tasks is not new and certainly understood by Ward Systems. Hopefully there'll be a day when such a capability will exist.

I think Steve has replied already on the multiple processor. As I stated, the DSP was a long time ago for Neuroshell not for NSDT and at that time the processors were indeed vey weak. Currently when I run NSDT on a dual processor only one is used by NSDT so having two seems of limited use. Steve explained that rel 5.0 should have this multiple cpu feature. Effectively, as you explain, if you run two instances at the same time each can use a separate processor. That however does not get round the problem of shortening the time to optimize.
Overall I tend to agree more and more with remarks by others (Mark Simpson in another thread) that if you spend too much time optimizing yo're probably barking up the wrong tree.

Maciej,

Thank you for your reply, The training results seems attractive (more than 5000% 0n 1 % margin), the lengthy time might be arised from the nature of the forex trade.

Good luck

It was not that I thought you didn't like the program, it was that I thought you were unsuccessful, and you assured me you were not.

I do not feel suggestions imply dissatisfaction with the program. In fact, most of what is in release 5.0 are suggestions from users. However, if we aren't moving fast enough, I would recommend that you and other users with suggestions help us by making sure we have resources to hire more personnel. After all, your original purchases several years ago do not help us now. You can help us by spreading the word about NeuroShell, and voting for us in the Technical Analysis of Stocks and Commodities competition. Prospective users heed more what old users say then they heed anything that Ward Systems says. So help us help you.

Suggestion for release 5 - max drawdown %

Date :10/24/2005 12:01:04 AM Poster : Jerry Wagner

Steve
Please include max drawdown expressed as a percentage. I run many long term research tests and the dollar drawdown is meaningless. Thanks

Too bad I can't "go back" to read your name. But this tip may help:

I get around the stops-by-percent-returns problem by converting my prices to "log-delta" format: Value= Accumulate(100 * (ln (PriceThisBar)- ln(priceLastBar))). This works well for me because my trading strategy is based on setting stops (stop order and limit order) optimized by the genetic algorithm optimised on "return", not optimised price crossing "signals" to execute at market price. That way, I can set my orders in place longer before they are executed, and not be tempted to chase sudden moves when its too late, and benefit by the random fluctuations above and below the trends, with "automatic execution" at more advantageous moments when the market is more liquid.

This "log-delta" view of returns translates price movements into percent changes such that doubling is "+100%" and halving is "-100%". It is different in that losses are treated same as gains, compared to the usual definition of percent change. If you double, its 100 points, and if you go back where you were before, you lose 100 points. It's percent relative to where you were on average the last two time points, not just where you are now. That way your stops expressed in terms of value are REVERSIBLY normalized to returns, both positive and negative. Otherwise you introduce an incorrect "bias" with increasing fluctuations even with longer term average price constant! Also, it helps when you are trying to compare one trading instrument to another by return on investment.

If you used stops based on the usual "percent change" definition you could get messed up by more meaninglessness than with dollar based stops.

Alternatively, you could simply express your prices in any logarithmic format you choose.

So my suggestion would be (for version 5) to have instant conversion to the logarithmic format that is representative of percent return built right into the program numerics and its charts: PRICE (dollar) format, and RETURN (unbiased percent-delta points) format. The only parameters needed would be starting (or ending) "points", and starting (or ending) time. From there, all trading instruments can be compared "apples-to-apples".

Re: Suggestion for release 5 - max drawdown %

Date :10/25/2005 3:43:40 PM Poster : Steve Ward

Rel 5.0 is already programmed and being tested as we speak, so it is really too late for enhancements (we're just fixing bugs now). But both of these suggestions are excellent, and they will be on our 5.1 or 5.2 list of prospective enhancements.

How does AdaptiveTurboprop2 retrain?

Date :10/24/2005 5:49:05 PM Poster : MFK

A question on day-to-day functioning of AdaptiveTurboprop2:

After initial optimization, when a net retrains, does it retrain all elements specified at setup (i.e., trainbars, aheadbars, hiddens, parameters for input indicators, etc.) or does it just retrain its internal weightings of parameters specified during original optimization?

Thanks.

Re: How does AdaptiveTurboprop2 retrain?

Date :10/26/2005 2:45:09 PM Poster : Ward.net Webmaster

AT2 only retrains weights. The other things you mentioned (trainbars, aheadbars, etc) are parameters for the training process itself, and they can only be changed by either you or the optimizer. Theoptimizer will only change them if you reoptimize. Once optimized, the net retrains itself every N bars using the parameters the optimizer found.

On 10/24/2005 5:49:05 PM MFK wrote:

Release 4.8

Date :10/27/2005 3:29:32 AM Poster : Sunny

I just tested release 4.8 this week, and I am happy to inform those of you that are interested in doing forex that it is apparently working right with e-signal for the first time.

This applies in particular to weekly and monthly charts. It is now showing correctly the date for the red bar (or actual bar) on either the current week or current month. Before this release this information was showing the next week or next month as being the actual bar.

This is particularly important for me as I can now make weekly or monthly forex predictions in the middle of the week rather than only on Mondays (as with release 4.7). :)

This in addition increases my confidence in the predictions since the information shown for the actual bar includes the actual data, and it is not broken as it used to be shown before. Nice going Ward Systems!

Quote.com missing data Oct 25

Date :10/27/2005 10:15:09 AM Poster : Ward.net Webmaster

Quote.com servers in Florida got zapped by hurricane Wilma and are missing data for Oct 25. Until they fix that (if they ever do) you should connect to servers in California. You can identify them because they have 214 in their IP addresses instead of 236. Load the file continuumclient.ini into Notepad from your NeuroShell folder and rearrange the entries so that some of the 214s are on top. Change autoupdateserverlist to false so quote.com won't rearrange them again. Below are the first few lines of our ini file to show you what to do. The first two servers listed have 214 in their IP addresses. (Please be aware that the continuumclient.ini file is not a Ward Systems file, and neither is the software that uses it. It is Quote.com software that we have no control over.)

AutoUpdateServerList=false
User=Wardsystems
Server=209.202.214.23:23100 65535 01/01/1801 00:00:00 (209.202.214.23)
Server=209.202.214.27:23100 65535 01/01/1801 00:00:00 (209.202.214.27)

Annual Support Fee

Date :10/28/2005 7:32:02 AM Poster : Michael J Begley

I respectfully suggest that diverting revenue from new customers to pay support costs for old customers is not a sustainable business model. I did vote in the TASC survey but this is not the answer to this problem.

I suggest figuring out what your support costs are, reduce if possible, and institute an annual charge to get them covered perhaps with a modest profit.

It will do none of us any good if new products and product upgrades are pushed out because support is draining resources away from that effort.

Ward Systems is a great company with great products and I would like to see you guys stick around for a long long time!!!

Thanks for listening.

Mike Begley

Re: Annual Support Fee

Date :10/28/2005 1:21:12 PM Poster : Maciej

On the surface your suggestion looks sensible. However there are two factors that should also be taken into account:
a) the sophistication of the NSDT precludes a "straight out of the box" approach so a forum / support are in my view indispensible. Just witness the type of questions that are discussed. The majority of users, I suggest, that have managed to harness the power of NSDT have invested considerable time into it. The product has got simpler to use but its clear that numbers of users abuse the freedom that one gets with the product.
b) whether we like it or not bugs do occur and it seems harsh to ask us to pay for bugs that shouldn't be there.

Re: Annual Support Fee

Date :10/31/2005 11:15:47 AM Poster : JPH

Another option would be to implement a modest charge for major releases ($50 to $100 say), while keeping 'point' releases free. Clearly a change in principle that could drift from modest cost support to expensive profit line over time. But backward release support issues would come into play if the more traditional optional upgrade choice model were to be followed, with if say the current and previous release both enjoying support.

Some more food for though.

John

Re: Annual Support Fee

Date :10/31/2005 7:04:00 PM Poster : Allan Kaminsky

Another model frequently used for 'serious' software is to allow the end-user a choice. Pay an annual maintenance fee (usually 15 - 20% of the purchase price) and get 'premium' telephone support, discounts on other products, and free upgrades on the maintained product (Mathematica, numerous other products use this model).

Users who choose to go the non-maintenance route get Email and forum support, pay upgrade fees.

I already pay annual maintenance for several products and would happily do so for NST. I want this company to succeed and will put my money where my mouth is!

TANSTAAFL.

Re: Annual Support Fee

Date :11/3/2005 7:17:40 AM Poster : Dan

I'd like to offer a very different perspective. Part of the reason NST and Ward stood out to me initially is that a.) they were honest, realistic and straightforward about the plusses and minuses of their product and b.) they were trying build relationships with their customers to help make them successful instead of squeezing them for every last penny at every turn.

NST is more expensive than some other products out there, but, once you buy, Ward takes care of you as a customer. That consideration was part of the purchase for me.

Personally, I've never bought a support contract in 15 yrs. of computer use. I think it is a way that companies put distance between themselves and customers they really don't want to deal with. I purchase as little as possible from such companies, knowing that I'm on my own with their products.

So, what I'd like to suggest is that support fees would take away something unique about the way Ward treats its customers, AND take away a salient selling point to prospective NST buyers.

Respectfully--

Dan Melton

Re: Annual Support Fee

Date :12/18/2005 2:29:29 PM Poster : stretto

I also feel that the availability of technical support as it is currently offered by Ward Systems is important to me as a user and was important to me as a prospective buyer. I also would prefer that the developers at Ward Systems spend their time improving the software rather than on the phone answering simple questions. Therefore, I would like to make a modest suggestion: update the Help file more frequently and/or expand it to include answers to the more commonly asked questions. Since it is all electronic, this would be easy to do. Incorporating the "Tips and Techniques" would also be helpful.

On 11/3/2005 7:17:40 AM Dan wrote:
I'd like to offer a very different perspective. Part of the reason NST and Ward stood out to me initially is that a.) they were honest, realistic and straightforward about the plusses and minuses of their product and b.) they were trying build relationships with their customers to help make them successful instead of squeezing them for every last penny at every turn.

NST is more expensive than some other products out there, but, once you buy, Ward takes care of you as a customer. That consideration was part of the purchase for me.

Personally, I've never bought a support contract in 15 yrs. of computer use. I think it is a way that companies put distance between themselves and customers they really don't want to deal with. I purchase as little as possible from such companies, knowing that I'm on my own with their products.

So, what I'd like to suggest is that support fees would take away something unique about the way Ward treats its customers, AND take away a salient selling point to prospective NST buyers.

Respectfully--

Dan Melton

On the surface your suggestion looks sensible. However there are two factors that should also be taken into account:
a) the sophistication of the NSDT precludes a "straight out of the box" approach so a forum / support are in my view indispensible. Just witness the type of questions that are discussed. The majority of users, I suggest, that have managed to harness the power of NSDT have invested considerable time into it. The product has got simpler to use but its clear that numbers of users abuse the freedom that one gets with the product.
b) whether we like it or not bugs do occur and it seems harsh to ask us to pay for bugs that shouldn't be there.

boolean indicator for strategy

Date :11/2/2005 4:21:33 PM Poster : Larry Burford

I have an indicator that begins with a rule (if/then) and ends with an output that is either 0 or 1. Why doesn't this qualify as a boolean indicator that can be used in a trade strategy?

Re: boolean indicator for strategy

Date :11/2/2005 4:52:13 PM Poster : Ward.net Webmaster

Try upgrading to release 4.8. It is our recollection that somewhere before 4.8, rules were added to the list of acceptable boolean indicators, even though they aren't always boolean. If you don't want to upgrade, try using A>B where A is your rule and B is zero.

On 11/2/2005 4:21:33 PM Larry Burford wrote:

Re: boolean indicator for strategy

Date :11/2/2005 7:59:15 PM Poster : Larry Burford

I am currently running v4.8. And I have experimented with several of the boolean rules as a preifx. Some show up in the Custom Indicator list when accessed from the Trade Strategy wizard, some do not. Is there a help file or other article available that talks about how to create a boolean indicator? Or is this a bug?

The indicators that show up in the list of acceptable booleans are those that NeuroShell know MUST produce boolean outputs (exception, IF which is there for convenience). If you make an IF indicator, then save it as a custom indicator, no it won't show up there. However, if you first save it on the chart, then you can insert it. We suppose it could be argued that we allow IF to be inserted at all, we should allow custom saved IFs to be inserted too. We'll put this on our list of things to be investigated.

previous values

Date :11/4/2005 9:43:23 AM Poster : Larry Burford

Is there a way to create a custom indicator (other than making a dll) that uses a lagged value of itself in the calculation?

Re: previous values

Date :11/4/2005 3:13:28 PM Poster : Ward.net Webmaster

No, the Indicator Wizard cannot build recursive indicators. However, if you have ever programmed anything at all, it is pretty easy to use BASIC to build DLLs. Programming a DLL is like programming a subroutine - no hard to learn I/O involved.

Cybernetic Analysis Add-on Package

Date :11/20/2005 3:19:15 PM Poster : Bob Swihart

Marge,

I enjoyed John Ehlers article, "Fractal Adaptive Moving Averages", in the October 2005 issue in the Technical Analysis of Stocks and Commodities Magazine.

I decided to purchase John Ehlers, Cybernetic Analysis Add-on Package, from Ward Systems Group.

I am very pleased with the Cybernetic Analysis because it definately helped me with my trading.

Now that I have used the package for some time, I think that anyone using Neuroshell Systems, should consider the Cybernetic Analysis Add-on Package.

I understand that Ward Systems will be selling John Ehlers Mesa Software add-on software in 2006. I am looking forward to using this system if it is anything as good as the Cybernetic Analysis add-on.

Sincerely,
Bob Swihart

Re: Cybernetic Analysis Add-on Package

Kurtosis and skewness

Date :11/29/2005 7:39:51 AM Poster : Sunny

I have been working lately with kurtosis and skewness.

Several different papers that I found suggest that these statistical tools could help to determine change in direction for time series of prices.

I was wondering if anyone here has indicators for these two measures.

Regards,

Sunny

Re: Kurtosis and skewness

Date :11/30/2005 4:15:41 AM Poster : Phil Greenwood

Sunny,

These are interesting measures - there is a compact discussion of calculating these numbers in Mathematics of Options Trading by C B Reehl - pp286-288. (I note that there is a citation in this book to Sheldon Natenburg). It appears that these calculations are pretty straightforward.

I presume you are wishing to compare short term skews and kurtosis to long term skews and kurtosis (or perhaps-erroneously-normal distribution)? If so, there may be some simple proxy approaches: A skew is going to appear when the market has been trending in a direction (in which case you will see a divergence of mean and median calculations). A sample with high kurtosis is likely to have elements of congestion and trending in it as opposed to one or the other; the diversity would account for the "fat tails" of high kurtosis.

However, perhaps you are considering your market's skewness and kurtosis with respect to the overall trading strategy? It seems to me that, in theory, using the GA to optimize over a sufficiently long sample period should take these effects into account..that is the large infrequent events should be factored into the data. The problem is what is a sufficiently long sample period? How many of these events need to be included?

Hope this is useful.

Phil

Re: Kurtosis and skewness

Date :12/1/2005 6:06:55 AM Poster : Sunny

Phil,

I am actually trying to go the way that Mark Simpson has suggested.
If I understand his approach, this means to predict without optimizing.

My understanting of the optimization process is that we are doing the "best" curve fit possible with the indicator at hand.

The approach I am trying to follow is to predict by training NS to find patterns. However, I am doing my best to avoid optimizing. It is a difficult trade off since my best results occur when I optimize, but my level of confidence is lower when I optimize.

Several interesting articles in the net suggest that these statistical measures when combined with other approaches appear to yield interesting results. In particular, look for articles from the Federal Reserve and from Cornell Univeristy.

A simple but untested approach is to look at the sign of kurtosis. If the sign is negative, and the sign of skewness is negative, then this would imply that prices will now go lower. On the other hand if kurtosis is negative and skewness is positive, then this could suggest that prices are going higher. However, I have been unable yet to test these ideas in NS.

Moreover, I do not think that these measures will suffice by themselves in accomplishing predictability. They would be part of a more comprehensive arsenal of tools. In addition, I think that several different time frames should be explored to confirm direction.

Regards,

Sunny

Hi,

Just to clarify, I'm not suggesting that you don't optimize coimpletely,
what I'm saying is.

1. With a regular approach, optimization should be the last thing, i.e. build a model that works then optimize it to improve results, don't optimize to build a working model unless you have enough data to validate your model, and the data you're modeling isn't changing fundamentally over time.

OR

2. Use a piecewise linear approach to a model, i.e. keep Degrees Of Freedom low,
and optimize frequently.

Re: Kurtosis and skewness

Date :12/4/2005 4:18:59 AM Poster : Sunny

Mark,

Thank you for setting me on the right path again.

As I said, I was not sure if I was understanding your approach correctly.

My understanding of the optimization process is that we are obtaining the "best" fit of something around a curve; however, I am always suspect that the future will bring some slow or fast curves that have not been seen in the past, and the optimization will fail to deal correctly with these.

For this reason, I thought that the approach of predicting patterns seemed more robust to me rather than to attempt to obtain a "best" fit for a curve by optimizing.

When you refer to "...a piecewise linear approach to a model...", are you thinking of having several different copies of the same prediction in which the maximum and minimum training set sizes vary.

For instance, I could have one copy of a prediction with a maximum of 6 years and a minimum of 4 years, and then I could have a second copy of the same prediction with a maximum of four years and a minimum of two years, and finally, I could have a third copy of the same prediction with a maximum of two years a minimum of one year. Finally, you would enter the results into a trading strategy, and you would allow the trading strategy to sort the results out.

By the way have you had any luck using kurtosis nad skewness?

That is always the danger. Which is why it necessary to keep an out of sample set
seperately to test on, or to paper trade the model.

To me, I don't see fast and slow curves, I see either data that hasn't been accurately modelled with a big enough sample set for the Degrees Of Freedom of the model, or I see an adaptive process in play that isn't being accurately modelled.

Essentially the optimizers job is to find the best fit. That's it goal, and it does a fine job of achivieing it. However there is no guarantee that the best fit is the best fit for the model as a whole.

For instance, if we toss a coin twice and we get tails both times, then you could build a perfect predictor that says, everytime we toss a coin we get tails. However we'd be wrong, because we modelled our results with total disregard to the model. (Not that
I'm suggesting we model a random process :-))

>When you refer to "...a piecewise linear approach to a model...", are you
>thinking of having several different copies of the same prediction in which
>the maximum and minimum training set sizes vary.
I'm talking about optimizing frequently, but it only works when the degrees of freedom are small. I've posted quite extensively on this a few months ago, please check these
out on the forum as they have diagrams explaining the proccess. Feel free to
ask questions if they don't address what you need to know.

>By the way have you had any luck using kurtosis nad skewness?
This comes into the probability type of indicators mentioned earlier. Stocks returns
aren't normally distributed, so technically assuming normality (as kurtosis and skewness, standard deviation do) could be considered a mistake. However at some level if you're measuring the extremeness of something, it's a reasonable approximation. I.E. You could say that if you had an
event that was way outside the norm, that it is
meaningful.

Other approaches can also be the fisher transform or even the log normal distribution
approach.

The probability approach works, provided you pick events that are extreme enough. However the catch is that these events are rare, so you're out of the market a lot of
the time. The more extreme the event, the more likely that you will get a reversal.

Mark,

"I'm talking about optimizing frequently, but it only works when the degrees of freedom are small."

If I have both a prediction and a trading strategy, once I have optimized both one time, then should I then optimize the next time from scratch or is optimization done using the last optimal settings?

"Stocks returns aren't normally distributed, so technically assuming normality (as kurtosis and skewness, standard deviation do) could be considered a mistake. However at some level if you're measuring the extremeness of something, it's a reasonable approximation. I.E. You could say that if you had an event that was way outside the norm, that it is meaningful."

Have you done actual experiments using kurtosis and skewness?

"Other approaches can also be the fisher transform or even the log normal distribution
approach."

My understanding of the fisher transform is that it is not suitable for non-stationary signals.

> done using the last optimal settings?
Personally I optimize from scratch, that way I know I'm always at the same starting point. However if you know that things haven't changed substantially, then optimizing from the last optimal settings will work fine too. But remember to specify the optimization
length.

I.E. If you optimized yesterday and were optimizing over a window of 3 days, then
the window would start from 3 days before yesterday. When you then re-optimize today, the window starts from 3 days before today etc.

> Have you done actual experiments using kurtosis and skewness?
Yes. Any biases tend to be transient in nature and identifiable by other means too.
However I recommend you go ahead an investigate it anyway, it helps with understanding probability type indicators. But make sure those percentages deltas are
logged (see earlier post), otherwise your results will be distorted.

> My understanding of the fisher transform is that it is not suitable for
> non-stationary signals.
I consider all of these approaches as less than ideal for non-stationary or infact anything other than a regular distribution. They are an approximation. Approximations can have a place however.

Ehlers Cybernetic Analysis For Stocks and Futures contains a good description of the Fisher Transform in Chapter 1.

Another way to improve the quality of results is to remove some of the non-stationarity before the analysis.

A simple indicator written in IBASIC

Date :11/29/2005 11:29:21 AM Poster : Steve Ward

I wanted to show everyone how simple writing indicators can be. Below is a simple indicator called ReducePrice we wrote in IBASIC ($49.99 at www.pyxia.com). This simple indicator just copies the input (close or whatever) multiplying it by 0.9. The count is the number of bars in the chart, in[] is the input array, and out[] is the output array. So it is an indicator that multiplies by 0.9:

```
export ReducePrice

sub ReducePrice(in[] as double, out[] as double, count as int)
def i as int

for i=0 to count-1
'multiply the input by 0.9 and return the result
out[i]=in[i]*.9
next i
return

endsub
```

The limitations of the eyeball test

Date :11/30/2005 4:35:59 AM Poster : Phil Greenwood

I had an insight that I wanted to share with the community here. I was reading Nassim Nicholas Taleb's book "Fooled By Randomness", pp95-97 "Bull and Bear Zoology", when I realized that there was a limitation in my intuition of how I was viewing trade indications...perhaps a few other people are struggling under this blind spot.

My simplistic approach has been that my systems should be capturing the meat of the moves. If the market went up, I should be long, or down, I should be short. Naturally this is ideal.

However, the trade signals that we identify when we optimize are something different; they are simply based on "expectation" - the aggregate product of the probabilies of outcomes and the value of those outcomes at any given point in time. And all of this is laboring under the twin interrelated assumptions that the indicators involved are meaningful, and that they will behave in the future as they did in the past as predictors of price action.

For example if, before our exit is triggered, there is a 30% chance of a 10% rise, and a 70% chance of a 2% fall we should be long! Even though the market is more likely to fall!

I know this is not simple; perhaps you're not making the same mistake, but then again, maybe you are? This is surely a limitation of eyeballing the strategy - in the chart you see the outcomes, not the probablities or expectations.

Problem with BarsSinceFill or BarsSinceActivated

Date :12/4/2005 11:31:26 PM Poster : Stephen

I am having problems with the BarsSinceFill or BarsSinceActivated (both = and >=) triggering prematurely. Using end of day data an order is generated for the following day. The following day the order is filled, but the BarsSinceFilled or BarsSinceActived is activated and a sell at market is issued for the next day. The trade is only open for a day, but the days since is = 15. Is there a problem with when the counter for the BarsSinceActived or BarsSinceFilled are reset ? I am using version 4.7.

Re: Problem with BarsSinceFill or BarsSinceActivated

Date :12/5/2005 1:27:25 PM Poster : Ward.net Webmaster

We don't think anything was fixed with them, and we aren't aware of any current bugs. First make sure you aren't exiting for some other reason. For example maybe the long/short entries exit short/long positions button is on, and an entry is causing the exit? Otherwise, send your chart to tech support. PS - list of bugs fixed in 4.8 is under Release News... on this site.

IBASIC

Date :12/9/2005 3:31:28 PM Poster : Steve Ward

I hate to keep harping on programming, but I get the sense many of you are wanting to build indicators too complex for the Indicator Wizard. www.pyxia.com has a holiday special on IBASIC Professional - $29.95. At that price you can't afford NOT to buy it. I keep hearing from users "I'm not a programmer." Then the next thing I hear is either "I know how to use Easy Language" or "I wrote FORTRAN and BASIC programs 20 years ago in college." With a little help from your friends here, I'm sure you could write complex indicators in IBASIC.

Re: IBASIC

Date :12/14/2005 5:41:25 PM Poster : JackR

If Ward would publish a complex example of using IBASIC it might help us "non-programmers". In the January issue of "Technical Analysis of Stocks and Commodities Marge says

"Users of NeuroShell Trader can go to the STOCKS & COMMODITIES section of the NeuroShell Trader free technical support website at www.NeuroShell.com to download a copy of the C code and corresponding DLL, along with a copy of the chart that includes the Swiss Army Knife indicator "(SWAK)

What about coding SWAK up in IBASIC and posting it here in the "Examples" section. The existing examples for IBASIC are a little thin. Since you are about to release 5.0 (hopefully) the developers should have a little time.

The issue is the time and effort required to learn the computer language, not the cost of the software. Many users may simply not have as much time as is needed- which is difficult to estimate ahead of time. If one wants to use a specific complex indicator, there are several options: 1) if it is available, you can buy the add-on 2) you can program it using the Indicator Wizard language, 3) you can hire someone to write the code for you, or 4) you can do it yourself- learn a programming laguage and write your own code. For simple indicators (like the example Steve Ward gave on his post of Nov 29), this is not necessary - simple indicators can be built with the Indicator Wizard language. When the indicators are more complex, it's harder to say- when does an indicator become (as you said in your post) "too complex for the Indicator Wizard"? At what point is it necessary to abandon the Indicator Wizard and write a .dll? If this was better understood, a better decision could be made. So, how about some information about the limitations of the Indicator Wizard language? Do you have an example of an indicator which is obviously too complex, and if so, why? How about one which is borderline- that could be done equally well either way?

Ninety % of our users will never need to program their own indicator. For the other 10%, it becomes an emergency when they read about some whiz bang indicator in a book or website, and it is too complicated for the Indicator Wizard. I'm trying to get that 10% prepared now. The irony to me is when they contact us for help, they say "I can't program" but invariably one of the following is true:

1. They wrote lots of Easy Langauge code for TradeStation
2. They programmed BASIC or FORTRAN in college
3. They can write ASP code for web sites

Excuse me, then YOU CAN PROGRAM! BASIC is not that hard.

Here are the main times I think you may have to resort to a program from the Indicator Wizard:

1. You need to do iteration or setting flags or values for later testing (although the Flag indicators in Advanced Indicator Set 2, as well as the Trigger and other indicators on this site will help a lot with those).
2. You need to build a recursive indicator (one that calls itself, or uses previous values of itself).
3. You wrote a lot of indicators in the Wizard but now your model is very slow (the Indicator Wizard is, after all, not a compiler but an interpreter).

Re: IBASIC

Date :12/19/2005 4:30:03 PM Poster : Steve Eberbach

The type of indicator I would (probably will, soon) write is not necessarily "complicated", but perhaps "difficult" using the Wizard. After all, such things as FFT or PCA are quite complicated, and there have been postings which might be translated to IBasic, such as the Maximum Entropy program on the forum (was in Power Basic).

I would think a simple Finite Impulse Response Filter with 32 coefficients would be damn hard with the wizard, and slow, too. But in Ibasic, just a modification of the sample Steve put up in the tips would do the job, and faster. The type of filters I plan to write myself are called "Hilbert Transform Filter", coefficients of which can be found as a java design program on Google, and several all-pass delay filters with delay less than one sample. I need to use a different filter design program to get these.

Your point is well taken that knowledge of one computer language transfers to another- you still have to learn the particular syntax of the new language, but the principles are similar. Perhaps the 10% of users for whom this is relevant will read this post and it will cut down on the aggravating calls to technical support.It's also true that some of us are better at it than others, and what seems obvious to an expert can be a struggle for a novice. Picking up the syntax can be relatively easy- learning to write and debug the algorithms is another story. At least that has been my experience. For most people it may not be worth it- just buy the add-on, and if it is not available, don't bother with it. Anyway, it seems useful to have some understanding of the limitations of the Indicator Wizard language, and hopefully not to have to learn everything through trial and error. Is it possible to look at a proposed model and say "this is way too much for the Indicator Wizard" (and avoid hours of futile computer time)? Numbers 1) and 2) below are pretty clear - what has been your (or other users) experience with #3? Where have you found the tipping point to be? I realize there is no precise answer, but I would be interested in what other users have found.

TWS 5.0 Release Prospects

Date :12/13/2005 4:58:50 PM Poster : JackR

In Steve's October newsletter he stated that 5.0 was in beta. At a presentation he made to a DC area technical trader's group about a year ago, Steve indicated that there would probably be a Broker order executing interface in 5.0. He said it would be an API type interface with one actual "working" interface to a real broker and sufficient information to adapt the API to other broker's APIs. Is this still the case?

Any clue as to when the beta will be debugged and ready for general release?

Re: TWS 5.0 Release Prospects

Date :12/15/2005 2:01:09 PM Poster : Steve Ward

Testing is coming along well and we are still planning to release not only a broker interface, but an interface to email trades as well.

One of my suggestions was to use the HyperOrder API - that way you can feed signals to many different broker feeds using a single interface. :)

John:

Here is a post from another thread -

In release 5.0 we will have a toolkit that will allow relatively easy hookup to several brokers, and one to Interactive Brokers already built in. Hyperorder will probably work with us to implement an interface.

So it looks like they will try to develop a Hyperorder interface. I guess Hyperorder is proprietary. Now if they would just release 5.0!

HyperOrder has a very simple API that you can access through a DLL. I have a JNI for it if you are into Java.

A HO interface will allow the software to link to; Interactive Brokers Workstation,
FXCM, RefcoFX, MAN FX?, Patsystems, MB Trading and MetaTrader. It can send emails when orders are raised. http://www.hypertrader.it/hyperorder.shtml.

I have no relations to this company BTW.

On Trusting Models...

Date :12/19/2005 8:15:50 AM Poster : Dan Melton

A question for any who would like to offer insight: At what point do you begin trusting your models enough to trade with them (i.e. what does a good checklist look like to you)?

Thanks for your thoughts--

Dan Melton

Re: On Trusting Models...

Date :1/3/2006 6:04:28 PM Poster : John Coleman

Some successful forward tests, and have a look at your accounts equity curve. You want it to be a smooth progressive increase if possible, and it should not mirror the equity curve of the security.

There are some useful stats that NST could/should include in its analysis to help with this IMHO.

John

One of my models

Date :12/23/2005 8:49:50 AM Poster : Steve Ward

There was a recent thread where people were asking what is a good model. I think I told someone they were expecting way too much for 2005 - which has been a really hard year. So I've put the performance results of one of my models on the web so you can see what I think is pretty good out of sample for this year. I'm actually thinking of selling signals made by it to anyone who either doesn't have NeuroShell or wants some decent signals while they are perfecting their own better models. Let me know what you think - we can discuss how good is good again if you want.

www.wardsystems.org/markettilt

You'll need Internet Explorer, Firefox won't read PowerPoint slides. You can phone me about this model, email me, or post here on the forum.

Re: One of my models

Date :1/5/2006 7:12:53 AM Poster : Dan Melton

Steve,

I think this is impressive, given that the signals are out of sample and the basket of stocks is so broad.

Dan Melton

The model has never been attempted on FOREX. We doubt it will work on that.

Steve,

You are selling signals with a ratio of gross profit / gross loss < 2.5 and a ratio of average winners to average losers < 2. You are basing your signals based on the equity (return on trades > 15%); however, what about the risk/reward ratio?

A ratio of average winners to average losers less than 2 means that you have a very small margin of error. If one of your winners turns to be a loser, then you will have to try to make up for it in the next series of wins, but this already assumes that the next series of trades will be winners. What happens if they are not winners? You have to make more trades to try to make up for your losers.

Moreover, in your stats for the dow 30 you have a % of profitable trades between 48 - 71%. This means flipping a coin would have done just as well with many of these trades -- 50% profitable trades.

Some of your sectors such as utilities have this ratio at less than one. This means that the utility sector would lose more than they win.

I would guess that the consecutive losers statistics would be greater than one. This would mean that you would have more than one consecutive loser.

In my humble opinion your system sounds kind of risky. If market conditions turn against you, will your system be able to compensate quickly for this?

Have you included already money management of your trades into your system, or are these raw signals?

Are you basing your signals based only on price and volume, or are you doing an inter- or intramarket model which takes other variables into account? For instance, are you including stock markets in other countries, interest rates, commodity prices, etc.?

Some people will accept these kinds of ratios; however, I would not trade them since the risk/reward ratio is not skewed in my favor. The whole point of trading short term is to have the cards stacked in my favor.

I am sorry, but I expected more from you.

Regards,

Sunny

No, Sunny, flipping a coin would not have produced these trades. Remember, I didn't do this model in hindsight, i.e., keeping the one that worked best in 2005. The model was trained once and hasn't been changed since May. Also, please read carefully - it is a SPY model that made almost 30% but whose signals happen to have general ability on the overall market. The signals aren't supposed to do great on every sector or every stock.

But I don't claim to be the best, and yes trading is risky. This model could fail. I am hoping you indeed have a better model, and are not just suffering from unrealistic expectations for 2005. I posted my model in the first place to fight the tendency people have to think this is still the nineties.

Re: One of my models

Date :1/15/2006 3:59:33 PM Poster : Maxwell Craven

I've long believed that appyling litmus tests to statistics is bad practice. Having said that, it doesn't look like you loaded the chart and applied to SPY, Sunny. It shows a return of 30.3%, with a gross profit/loss ratio of 2.86, and 62.8% profitable trades. Max drawdown is only $522, and open trade drawdown of only $233. I don't know about you, but I have no chart that good, unless I train or optimize on 2005, which Steve says he didn't do.

iBasic : Column by Column Processing (BYREF)

Date :12/27/2005 4:07:59 PM Poster : Stephen

When using iBasic to build a custom indicator that is using a Neuroshell indicator outputs as inputs to the custom indicator how do you ensure that the custom indicator is called after the Nueroshell indicators have finished? In other words if thinking like a spreadsheet, performing column by column processing (BYREF processing), column A (Neuroshell indicator result) has to be computed before column B (custom indicator result) is calculated. Does Neuroshell perform column by column processing or row by row processing?

Re: iBasic : Column by Column Processing (BYREF)

Date :12/27/2005 4:49:05 PM Poster : Ward.net Webmaster

NeuroShell does that for you so you don't have to worry. It knows what things feed into what (dependencies), so it calculates them in the correct order. It will not call your IBASIC code until all the inputs you are passing to it are available. We think spreadsheets do the same thing; we doubt they go column by column or row by row. BYREF usually just means you are passing pointers to the data, not passing the data itself.

On 12/27/2005 4:07:59 PM Stephen wrote:

iBasic: currentbar ? index into array

Date :12/27/2005 8:39:18 PM Poster : Stephen

For the iBasic function below I need the currentbar, which I use as the index into the array of values high,low,close to extract the days of interest. This function is made to be called row by row but I assume the whole array (vector) of price information is passed. How do I get the current bar number? What are the bounds on the current bar number so I can bounds check the index when it is passed to the dll?

```
export TrueRange

'Find the Maximum Value of two double floating point numbers

sub Max(value1 as double, value2 as double), double
def result as double
result = value1
if result < value2 then result = value2

return result
endsub

'Find the TrueRange
sub TrueRange(high[] as double, low[] as double,close[] as double, currentbar as int, out as double)

def value1 as double
def value2 as double
def value3 as double

if currentbar = 1
out = high[currentbar] - low[currentbar]
else
value1 = high[currentbar]-low[currentbar]
value2 = high[currentbar]-close[currentbar-1]
value3 = close[currentbar-1]-low[currentbar]
out = Max(value1,value2)
out = Max(out,value3)
endif
return
endsub
```

Re: iBasic: currentbar ? index into array

Date :12/28/2005 11:27:22 AM Poster : Steve Ward

There are two ways to call a subroutine in a DLL from NeuroShell:

1. Byvalue - each time the subroutine is called, NeuroShell passes in all the inputs you have specified for the current bar only. So if there are 1000 bars in the chart, the subroutine is called 1000 times, once for each bar in the chart. Each time it is called, you will have access to only the values for the current bar. This may be what you have been calling column by column.

2. ByArray - the subroutine is called only once. NeuroShell passes in all the inputs you have specified, each in its own array. Each array contains all the bars in the chart for that particular input, so if you are passing open, high, low, and close there will be an array for each. If there are 1000 bars, each array has 1000 elements in it. Each time the subroutine is called, therefore, you have access to ALL the bars in the chart for each input. You are also responsible for providing the output for all bars at once. This may be what you have been calling row by row. In this mode, you need access to the number of the bars in the chart (i.e., the number in each array). That is a value you can pass into the subroutine when you call the indicator "External DLL call by array" . It is called "As the number of values in the time series input(s)". You describe it where you describe the output.

If the TrueRange indicator you are writing referred only to the current bar, you could have used ByValue, but it looks at the previous bar too, so you have to use ByArray. So you have to sent up a parameter in which you receive from NeuroShell the number of bars in each array. You iterate through the whole array (starting at 0). I've re-written your main subroutine a little to show you how it is done:

```
export TrueRange

'Find the TrueRange
sub TrueRange(high[] as double, low[] as double, close[] as double, barcount as int, out[] as double)

def value1 as double
def value2 as double
def value3 as double
def currentbar as int

for currentbar=0 to barcount-1 ' iterate through bars - one at a time

if currentbar = 0 then ' this is the oldest bar, and has no previous
out[currentbar] = high[currentbar] - low[currentbar]
else
value1 = high[currentbar]-low[currentbar]
value2 = high[currentbar]-close[currentbar-1]
value3 = close[currentbar-1]-low[currentbar]

out[currentbar] = Max(value1,value2)
out[currentbar] = Max(out[currentbar],value3)
endif

next currentbar

return
endsub
```

On 12/27/2005 8:39:18 PM Stephen wrote:

endif
return
endsub
```

iBasic: return types

Date :12/28/2005 2:58:15 PM Poster : Stephen

Thanks, Steve

Just to make sure I understand the concepts, I rewrote the TrueRange indicator to a ByVal (row by row or bar by bar) form. This would not be as efficient as ByRef for this particular indicator, but I have other indicators I would like to write as this form. Also, I changed the return value is sent back to Neuroshell. To get the prior close I use the lag indicator built into Neuroshell. Does this look correct?

Also, to pretty up code, is there anyway to write the following "C" code in iBasic?

```
#define NAN 3.4e38
```

The constant construct only accepts UINT.

Re: iBasic: return types

Date :12/28/2005 3:38:21 PM Poster : Steve Ward

Yes, that looks right to me, except you'll probably need:

```
def out as double
```

I think you have mastered both types of calls. Compile and run it to make sure it gives the same values as the other one.

For the constant 3.4e38, which as you must already know is what you put in the output stream where you want a blank instead of a number, I usually just do this:

```
def missing as double
missing = 3.4e38
```

On 12/28/2005 2:58:15 PM Stephen wrote:
Thanks, Steve

Just to make sure I understand the concepts, I rewrote the TrueRange indicator to a ByVal (row by row or bar by bar) form. This would not be as efficient as ByRef for this particular indicator, but I have other indicators I would like to write as this form. Also, I changed the return value is sent back to Neuroshell. To get the prior close I use the lag indicator built into Neuroshell. Does this look correct?

Also, to pretty up code, is there anyway to write the following "C" code in iBasic?

```
#define NAN 3.4e38
```

The constant construct only accepts UINT.

Thanks,

Stephen

Re: iBasic: return types

Date :12/29/2005 3:02:52 PM Poster : Steve Ward

I suppose I should add that the proper True Range Indicator needs the absolute values of the differences:

value1 = abs(high-low)
value2 = abs(high - prior_close)
value3 = abs(prior_close - low)

suggestions: order processing/analysis

Date :1/3/2006 5:58:52 PM Poster : John Coleman

1) It would be nice if NST had a hook up to HyperOrder. Their DLL is easy to interface to, and that way orders can be fed to most of the popular brokers.

2) I'd like to see more analysis features built in, like an account equity curve, sharp ratio, all that usual stuff. At present it seems one has to work this stuff out using a spreadsheet.

Any idea if these could get into a future release?

Re: suggestions: order processing/analysis

Date :1/4/2006 8:48:13 AM Poster : Ward.net Webmaster

As a new user you may not have noticed all the equity curves we have. They are indicators, and you will find them in the category Trading Strategy: System Information". The Trading Strategy: Position Information has some good analysis tools too. Also, you may not yet have turned on all of your Wizard options. Go to Tools->Options-> Wizards. Do a Select all on all of the wizards.

The Sharpe ratio is in the optimizer. You'll find it as one of the objective functions.

In release 5.0 we will have a toolkit that will allow relatively easy hookup to several brokers, and one to Interactive Brokers already built in. Hyperorder will probably work with us to implement an interface.

Suggestion on forum software

Date :1/7/2006 12:07:44 AM Poster : John Takacs

Greetings!

I wonder if a possible reason for the low turnout on this forum is the forum software used?

I cringe in pain every time I come here.

Being able to see all threads instantly would be great. Instead I have to click the "+" to open a thread, and then patiently wait for the 386 PC ;-) server to load the new page. This is not quite as bad as watching paint dry, but it is close.

Webmasterworld.com uses an excellent forum software. The great folks at gossamer-threads.com have a forum software for sale as well. I use their directory software on my search engine web site (1996).

I really think this forum could become a mini slashdot for traders, but the stumbling block is the forum software.

Finally, I have a 10 Mbps in country (South Korea) connection and overseas (to USA) I top out at 2 Mbps (2000 Kbps).

Regards,

John

Re: Suggestion on forum software

I +1 that suggestion. Tnx John.

Re: Suggestion on forum software

Date :1/14/2006 8:58:25 AM Poster : Jacobs

Hello,

If I read the postings within 7 days the software is fine.

If I been away for more than 7 days it´s very hard to know which postings has
been written since last time.

If I find a topic with many postings it´s very hard to read them in the correct
order. They seem to be sorted in their own logic = not by date, which I haven´t found out.

I would like see a complete list (like the list now if less than 7 days old) of all the postings since I last logged on,
a list of those that I haven´t yet read.

Regards,
/J

Writing an NN

Date :1/7/2006 11:25:40 AM Poster : John Takacs

I have an idea for an NN that has nothing to do with a trading system or an indicator. It is an exit strategy type of idea. It could be more than that but here goes the description:

1) Pick your most important period moving average. The one that seems to best indicate the overall trend of your market of choice on a 5 minute bar. So, for example, let's say you like the 47 period MA.

2) If prices are beneath the 47 period MA (having tanked earlier) and are coming back to approach the 47 period MA from the bottom, perhaps over 3 - 6 bars, then you want to predict the likelihood of prices stopping at the 47 period MA and being a percentage below the 47 period MA in the next X number of bars vs continuing on through the 47 period MA, and being a percentage above the 47 period MA.

Bottom line, in the above example, knowing that prices for the current situation are going to stop at the 47 period MA would give you a edge to continue or initiate an additional short trade.

John

Re: Writing an NN

Date :1/8/2006 8:31:42 AM Poster : Matt Jarvis

Thats not a bad idea. I'd suggest using the spread between the price and the moving average, or the rate of change of the spread, maybe feeding those both into recur2 or recur2c.

DLL documentation or hints

Date :1/13/2006 5:46:10 PM Poster : Michael Stigall

I'm interested in creating some DLLs to perform some data analysis. Specifically, I want to find a likely stock option when the NST trading system gives a new buy/sell indicator.

What series do I need to pass to the DLL to duplicate the red/blue arrows output on the chart, and how do I pass them to IBasic?

Thanks.

Re: DLL documentation or hints

Date :1/14/2006 1:11:56 PM Poster : Ward.net Webmaster

What you would do is build your trading signals in a DLL. Then interrogate the output of your DLL in the Trading Strategy Wizard. The DLL can't put the red/blue triangles out directly. So your conditions could be something like this:

A>B (your DLL output, something) Long Entry

A

Re: DLL documentation or hints

Date :1/20/2006 9:59:31 PM Poster : Michael Stigall

I already have a NST trading system which outputs the buy/sell/exit/entry flags on the chart. I'm wondering if you have any documentation on the interpretation of the buy/sell/exit/entry flags (which show up as binary flags within output text file)?

The flags are represented by:
PRED > Long entry threshold
PRED < Long exit threshold
PRED < Short entry threshold
PRED > Short exit threshold

Each of these conditions seem to output as boolean values (true or false, 1 or 0). However, the NST chart seems to look at the previous day's values and compares them to current day to determine where the blue/red exit/entry arrows are placed. Is this documented?

Other data from eSignal

Date :1/14/2006 6:41:47 PM Poster : TRice

Is it possible to get data on a stock from eSignal other than open, high, low, and close? For example, is there a way to get for INTC the PE, Beta, and DivYld, which I can get on an eSignal quote page (.quo)?
Thanks

Re: Other data from eSignal

Date :1/17/2006 11:16:34 AM Poster : Maciej

Trading futures, I'm interested in using Open Interest for the feeds. As far as I can see it's not possible to customize the data feed to include/exclude available fields (possible enchancement for Ward to consider). I have to resort to exporting data from my data feed to say CSV format and then reading it from NSDT. OK if a bit tedious for daily data but not really practical with smaller timeframes.
It may be possible to write your own interface but that seems like a lot of work.

On 1/14/2006 6:41:47 PM TRice wrote:

> OK if a bit tedious for daily data but not really practical with smaller timeframes.

No the intraday feeds are not customizable. On the other hand, open interest is not something that changes on an intraday basis either. If you feed daily open interest into your intraday chart, it should show up on every bar - of course it will be the same value on every bar too. Daily feeds that you download should read open interest just fine, as well as anything else they provide on a daily basis, like fundamental data. So those who want fundamental data or other data that does not change intraday are advised to use a daily download instead of an intraday feed.

No the intraday feeds will not read what is essentially daily or even quarterly data. On the other hand, those things are not something that change on an intraday basis either. If you feed daily open interest, etc. into your intraday chart from a text file, it should show up on every bar - of course it will be the same value on every bar too, and so we question their use on an intraday chart. Daily feeds that you download should read open interest just fine, as well as anything else they provide on a daily basis, like fundamental data and the other things you mention. So those who want fundamental data or other data that does not change intraday are advised to use a daily download instead of an intraday feed. By the way, you can compute Beta yourself - we have a tip on that.

Re: Other data from eSignal

Date :1/24/2006 3:58:25 PM Poster : Ward.net Webmaster

We should also add that this fundamental data from eSignal is not historical. To the best of our knowledge, all you can get is a current snapshot, which would not be of much use in building models in NeuroShell. If anyone knows of a feed that supplies streaming historical fundamental data at a reasonable price, let us know (post here) and we'll try to support it. Most likely it will NOT be intraday, only daily, so we probably already do support the format.

On 1/20/2006 9:18:04 AM Ward.net Webmaster wrote:

iBasic: return byVal usage

Date :1/16/2006 9:15:14 PM Poster : Stephen

I am trying to use iBasic and Neuroshell byVal custom DLL calls. Below is my test of using the return from the function as the indicator output. Even sending close as a constant numeric 5 did not return anything. What am I missing in the setup of the Custom DLL calls ?

```
---------------------------------------------------------------------------------------------------
export CloseReturn

'Close Echo Test, Close sent byVal as double as Numeric, return used as indicator output byVal double

sub CloseReturn(Close as double), double

Close = Close + 1

return Close
endsub
---------------------------------------------------------------------------------------------------
```

Re: iBasic: return byVal usage

Date :1/18/2006 11:20:09 AM Poster : Ward.net Webmaster

Stephen,

This piece of IBasic code should work:

```
---------------------
export CloseReturn

declare cdecl CloseReturn(Cl as double), double

sub CloseReturn(Cl as double), double
return Cl+1
endsub
---------------------
```

The key to success is to use the cdecl modifier to explicitly specify the calling convention. After cdecl is used, you cannot use "Close" anymore as variable name. Therefore, we changed that to Cl. We actually compiled the dll and tested it in the NST. It worked just fine.

Re: iBasic: return byVal usage
Date :1/19/2006 11:11:12 AM Poster : Ward.net Webmaster
A little further explanation might be in order. The cdecl isn't required when sending back data in an array. In IBasic it is apparantly only required when passing data thru the stack as a function return. Since we have not used that method ourselves in IBasic before, we didn't realize it either until you brought it up.

On 1/18/2006 11:20:09 AM Ward.net Webmaster wrote:
Stephen,

This piece of IBasic code should work:
---
export CloseReturn

declare cdecl CloseReturn(Cl as double), double

sub CloseReturn(Cl as double), double
return Cl+1
endsub

The key to success is to use the cdecl modifier to explicitly specify the calling convention. After cdecl is used, you cannot use "Close" anymore as variable name. Therefore, we changed that to Cl. We actually compiled the dll and tested it in the NST. It worked just fine.

I am trying to use iBasic and Neuroshell byVal custom DLL calls. Below is my test of using the return from the function as the indicator output. Even sending close as a constant numeric 5 did not return anything. What am I missing in the setup of the Custom DLL calls ?

---
export CloseReturn

'Close Echo Test, Close sent byVal as double as Numeric, return used as indicator output byVal double

sub CloseReturn(Close as double), double

Close = Close + 1

return Close
endsub

Renaming indicators
Date :1/18/2006 2:06:55 PM Poster : Phil Greenwood
I've noticed that when you rename an indicator, you can't see the optimized settings of its parameters in the trading strategy results trading rules window.

Is there any way of backing out the naming so that the parameters are visible again? (Since I build a trading strategy on this indicator, it's a lot of work to re-do it all.)

Thanks,
Phil

Statistics on Current Market High going Higher or Current Market Low Going Lower
Date :1/20/2006 11:40:27 AM Poster : John Takacs
I was wondering if the Day Trader Professional has the ability to give me cold hard statisitcs on the following scenario:

Let's say the 30 year bond had a high of 114 26 today, and is now sitting at a low of 114 12 for the day. Let's say, I had stepped away from my desk, missed the earlier short trade and now find myself looking at the "as of this moment" low of the day. What are the statistics that based on a 14 tick down move off of the high that the market will continue lower. Reverse the scenario for a move off the high of the day.

If Day Trader Pro won't do it, any ideas?

We're confused, perhaps by your use of the word statistics. Are you asking how to build a model to predict that the market will move lower once it has dropped 14 ticks? Or are you asking how many times in the past did a 14 point drop precede another drop? If the latter, take a look at our new Pattern Matcher add-on.

Forcing NN to leave one rule alone
Date :1/20/2006 11:44:12 AM Poster : John Takacs
I have a situation where I trade off of a long term moving average on the 5 minute chart, let's say 44. If I input a buy/sell rule and have two criteria, i.e. only go long if RSI is blah blah, and closing price is above 44 MA, the NN will sometimes throw out the 44 MA. How do I avoid that?

Re: Forcing NN to leave one rule alone
Date :1/20/2006 5:23:13 PM Poster : Ward.net Webmaster
We have to ask, if you have such specific rules, why are you using a neural net at all instead of a trading strategy? What are you telling the net to do and what exactly are you feeding it?

After pondering your question more, we've decided you've use "NN" to refer to the genetic algorithm optimizer optimizing a trading strategy. If that be the case, here's the answer: either don't optimize or optimize with parameter search. Rule selection and Full optimization throw out rules.

Well, in the past only taking long trades when the price is above the 50 MA and only taking short trades when the price is below the 50 MA has saved me more times than I can remember.

The above would be an example of a rule that I don't want changed or is the word adapted? In addition to not adapting the above, I don't want the above thrown out either, as is currently happening.

"Why use a neural net at all?" That is kind of a disturbing question. I'd lilke to setup a multiple indicator system without the end result being that only one indicator remains at the end. Is this not possible?

Scenario: Based on personal experience, I know that the above 50MA rule works. Based on experiments with DayTrader Pro, I know that I can find a single indicator and adapt it and it will work by itself. Knowing that I would never take a trade that violated the 50MA rule, I'd like to add 2 rules together, i.e test my 50MA rule with RSI, CCI etc.

Should be easy right? So far, anytime I have 2 or more rules in the go long / go short section, without fail, one rule is thrown out, and only one remains.

I'm I doing something wrong?

I've seen your type of problem. In a trading strategy when optimising it seems difficult to use the option "if 2 are true" where 2 can be any number. I use a different approach. I would and your 50MA rule with each one of the other rules and then let the optimiser select the best parameters. This way you're forcing NSDT to use your obligatory rule. So each indicator would be in the format: and(RSI, MA(close,50)) and you'd lock the value 50 not to change. Slightly tedious but it should do the trick.
There are other ways of doing something similar but I'll let others suggest their way - it might be more efficient.

Keltner Channels

Date :1/20/2006 5:27:26 PM Poster : John Coleman

Anyone know how I can get them into my studies?

TIA
John

Targets question

Date :1/25/2006 1:42:21 PM Poster : Manny L.

I almost always find that my best out of sample returns using the Prediction Wizard in NST come from using a short lookahead (1 day usually) on percent change in open. It has always seemed to me that such a noisy target function makes the NN's job of getting good correlation with it near impossible. Yet, when I try smoother targets that inherently have better correlation with the inputs, the returns are not as good even though the out of sample signal correlates much better with the target. Is there an explaination for this behavior and is there an optimal way to develop target functions based on a given input set? Anybody else notice this? Any thoughts on the subject would be much appriciated.

> When you smooth your target, you will be adding a delay unless you compensate for it. A smooth moving average pushed ahead one bar is mostly made up of the past data. You would, for example, need to set the delay of a 3-bar moving average from 1 bar past (natural delay lagging) to one (or more) bar future (leading) in order to get an apples/apples comparison with your one bar future (leading) percent change target. That would be using at least 2 bar lookahead for a three bar moving average to get a "real" one bar lookahead.

Different Objectives in Trading Strategy

Date :1/27/2006 3:25:48 AM Poster : Maciej

Can anyone point me in the direction of where to look to setup a trading strategy objective that's different from the current list of possibilities? Essentially I wish to use one of the existing objectives such as (winners-losers*profits) and multiple it by the number of bars in the trade.
